Published <i>With international search report.</i>	
(54) Title: BETA-DEFENSINS			
(57) Abstract The present invention relates to polynucleotide and polypeptide molecules for zampl, a member of the beta-defensin family. The polypeptides, and polynucleotides encoding them, exhibit anti-microbial activity and may be used in the study or treatment of microbial infections. The present invention also includes antibodies to the zampl polypeptides.

BETA-DEFENSINS

5

BACKGROUND OF THE INVENTION

Biological defense strategies have evolved to protect organisms from invasion by other species. Microbial infection response systems include oxidative and non-oxidative mechanisms, utilizing compounds that are enzymatically synthesized in cells and peptides that are single gene products.

Anti-microbial peptides constitute an oxygen-independent host defense system found in organisms encompassing many taxonomic families. One major class of anti-microbial peptides can be sequence-defined by conserved cysteine residue patterns and are termed defensins. Mammalian defensins, derived from skin, lung and intestine, exhibit antibiotic activity against a wide variety of pathogens, including gram-positive and gram-negative bacteria, fungi (e.g., *Candida* species) and viruses. See, for example, Porter et al., Infect. Immun. 65(6): 2396-401, 1997.

The amphipathic character of the defensin peptides appears to be the key to the general mechanism of microbial attack, i.e., by creating pores, or "boring" through the cell wall. In addition, Daher et al., J. Virol. 60(3): 1068-74, 1986, reported that enveloped viruses, including herpes simplex types 1 and 2, cytomegalovirus and influenza virus (A/WSN), among others, were inactivated by incubation with human neutrophil peptide (HNP-1) and speculated that the binding of defensin molecules to viruses impairs the virus' ability to infect cells.

The defensin family of anti-microbial peptides can be divided into two major subclasses based on two

distinct consensus sequences. See, for example, Martin et al., Journal of Leukocyte Biology 58: 128-36, 1995. The first defensin subclass, classic defensins, represented by HNPs are stored in the so-called large azurophil granules of neutrophils and macrophages and attack microorganisms that have been phagocytosed by these cells. The amino acid sequence of HNPs is consistent with a predicted disulfide bridging that is distinct from that of the β -defensin subclass. Epithelial cells can also be a source of defensins, and these cells appear to secrete these peptides into the external, extra-cellular environment. In the mouse, for example, Paneth cells of the small intestine and proximal colon, secrete defensin-like peptides, called cryptidins, into the lumen. See, for example, Ouellette and Selsted, The FASEB Journal 10: 1280-9, 1996.

β -defensins, the second major defensin subclass, include peptides found in bovine lung (e.g., BNBD-bovine neutrophil β -defensins) as well as a secreted form (TAP - tracheal anti-microbial peptide). See, for example, Selsted et al., J. Biol. Chem. 268(9): 6641-8, 1993. Two human β -defensins have been reported. SAP-1 was isolated from human psoriatic skin, and hBD-1 was found in low concentrations in human blood filtrate. See, for example, Bensch et al., FEBS Lett. 368(2): 331-5, 1995). The amino acid sequence of these human β -defensins is most similar to the bovine BNDPs and TAP. See, for example, Harder et al., Nature 387: 861, 1997, wherein SAP-1 is designated hBD-2.

Other than the conserved cysteine residues the defensin family is quite sequence divergent. It is possible that the variant amino acid positions may be related to the site or conditions of activity or to the spectrum of pathogens attacked by a particular defensin.

In addition to anti-microbial activities, particular defensins exhibit metabolically sensitive cytotoxic activity (Lichtenstein et al., Blood 68: 1407-

BETA-DEFENSINS

5

BACKGROUND OF THE INVENTION

Biological defense strategies have evolved to protect organisms from invasion by other species. Microbial infection response systems include oxidative and non-oxidative mechanisms, utilizing compounds that are enzymatically synthesized in cells and peptides that are single gene products.

Anti-microbial peptides constitute an oxygen-independent host defense system found in organisms encompassing many taxonomic families. One major class of anti-microbial peptides can be sequence-defined by conserved cysteine residue patterns and are termed defensins. Mammalian defensins, derived from skin, lung and intestine, exhibit antibiotic activity against a wide variety of pathogens, including gram-positive and gram-negative bacteria, fungi (e.g., *Candida* species) and viruses. See, for example, Porter et al., Infect. Immun. 65(6): 2396-401, 1997.

The amphipathic character of the defensin peptides appears to be the key to the general mechanism of microbial attack, i.e., by creating pores, or "boring" through the cell wall. In addition, Daher et al., J. Virol. 60(3): 1068-74, 1986, reported that enveloped viruses, including herpes simplex types 1 and 2, cytomegalovirus and influenza virus (A/WSN), among others, were inactivated by incubation with human neutrophil peptide (HNP-1) and speculated that the binding of defensin molecules to viruses impairs the virus' ability to infect cells.

The defensin family of anti-microbial peptides can be divided into two major subclasses based on two

10, 1986 and Sheu et al., Antimicrob. Agents Chemother. 28: 626-9, 1993), alter the response of adrenal cortical cells to ACTH (Zhu et al., Proc. Natl. Acad. Sci. (USA) 85(2): 592-6, 1988) and have specific chemotactic activity 5 for human monocytes (Territo et al., J. Clin. Invest. 84(6): 2017-20, 1989). Recruitment of monocytes by neutrophils may, in part, be mediated by neutrophilic defensins and suggests a pro-inflammatory activity for these peptides in addition to their anti-microbial 10 effects. Also, a decrease in defensin mRNA level has been demonstrated in SPG (specific granule disease). See, for example, Tamura et al., Japan. Int. J. Hematol. 59(2): 137-42, 1994. Higazi et al., J. Biol. Chem. 271(3): 17650-5, 1996, suggested that plasminogen bound to fibrin in the 15 presence of defensin may be less susceptible to activation by tPA.

Moieties having anti-microbial, immunostimulatory, pro-inflammatory and other properties of defensins are sought. The present invention provides 20 such polypeptides for these and other uses that should be apparent to those skilled in the art from the teachings herein.

SUMMARY OF THE INVENTION

25 Within one aspect the invention provides an isolated protein comprising a polypeptide that is at least 80% identical to a polypeptide selected from the group consisting of: a) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 65 of SEQ ID 30 NO:2; b) a polypeptide having the sequence of amino acid residue 19 to amino acid residue 65 of SEQ ID NO:2; c) a polypeptide having the sequence of amino acid residue 21 to amino acid residue 65 of SEQ ID NO:2; d) a polypeptide having the sequence of amino acid residue 1 to amino acid 35 residue 67 of SEQ ID NO:10; e) a polypeptide having the sequence of amino acid residue 21 to amino acid residue 67 of SEQ ID NO:10; and f) a polypeptide having the sequence

of amino acid residue 23 to amino acid residue 67 of SEQ ID NO:2; wherein the polypeptide has cysteine residues corresponding to amino acid residues 33, 40, 45, 55, 62 and 63 of SEQ ID NOs:2 or 10. Within one embodiment the
5 protein comprises a polypeptide having the sequence selected from the group consisting of: a) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 67 of SEQ ID NO:10; b) a polypeptide having the sequence of amino acid residue 21 to amino acid residue 67
10 of SEQ ID NO:10; and c) a polypeptide having the sequence of amino acid residue 23 to amino acid residue 67 of SEQ ID NO:10.

Within another aspect is provided an isolated protein having the sequence of SEQ ID NO:10 from amino
15 acid residue 23 to amino acid residue 67.

Within still another aspect is provided a pharmaceutical composition comprising a protein as described above in combination with a pharmaceutically acceptable vehicle.

20 Within yet another aspect is provided an antibody that specifically binds to a protein as described above.

Within a further aspect is provided an anti-idiotypic antibody of an antibody which specifically binds
25 to a protein as described above.

Within another aspect is provided an isolated polynucleotide molecule encoding a protein, the polynucleotide molecule consisting of a coding strand and a complementary non-coding strand, wherein the
30 polynucleotide molecule encodes a polypeptide that is at least 80% identical to the amino acid sequence to a polypeptide selected from the group consisting of: a) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 65 of SEQ ID NO:2; b) a polypeptide
35 having the sequence of amino acid residue 19 to amino acid residue 65 of SEQ ID NO:2; c) a polypeptide having the sequence of amino acid residue 21 to amino acid residue 65

of SEQ ID NO:2; d) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 67 of SEQ ID NO:10; e) a polypeptide having the sequence of amino acid residue 21 to amino acid residue 67 of SEQ ID NO:10; and
5 f) a polypeptide having the sequence of amino acid residue 23 to amino acid residue 67 of SEQ ID NO:2; wherein the polypeptide has cysteine residues corresponding to amino acid residues 33, 40, 45, 55, 62 and 63 of SEQ ID NOs:2 or 10.

10 Within another aspect the invention provides an isolated polynucleotide molecule encoding a protein having cysteine residues corresponding to amino acid residues 33, 40, 45, 55, 62 and 63 of SEQ ID NO:10, the polynucleotide molecule consisting of a coding strand and a complementary
15 non-coding strand, wherein the polynucleotide comprises a nucleotide sequence that is at least 80% identical to the sequence of a polynucleotide selected from the group consisting of: a) a polynucleotide as shown in SEQ ID NO:9 from nucleotide 220 to nucleotide 420; b) a polynucleotide
20 as shown in SEQ ID NO:9 from nucleotide 280 to nucleotide 420; and c) a polynucleotide as shown in SEQ ID NO:9 from nucleotide 286 to nucleotide 420.

Within yet another aspect is provided an isolated polynucleotide molecule encoding a protein having
25 cysteine residues corresponding to amino acid residues 33, 40, 45, 55, 62 and 63 of SEQ ID NO:10, the polynucleotide molecule consisting of a coding strand and a complementary non-coding strand, wherein the polynucleotide comprises a nucleotide sequence as shown in SEQ ID NO:11.

30 Within still another aspect is provided an expression vector comprising the following operably linked elements: a transcription promoter; a DNA segment encoding a protein as described above; and a transcription terminator. Within one embodiment the DNA segment further
35 encodes a secretory signal sequence operably linked to the protein. Within a related embodiment the secretory signal sequence is selected from the group consisting of: a) a

polypeptide having the sequence of amino acid residue 1 to amino acid residue 18 of SEQ ID NO:2; b) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 20 of SEQ ID NO:2; c) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 20 of SEQ ID NO:10; and d) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 22 of SEQ ID NO:10.

Within another aspect the invention provides a cultured cell into which has been introduced an expression vector comprising the following operably linked elements: a transcription promoter; a DNA segment encoding a protein as described above; and a transcription terminator; wherein the cell expresses the protein encoded by the DNA segment.

Within a further aspect is provided a method of producing a protein comprising: culturing a cell into which has been introduced an expression vector comprising the following operably linked elements: a transcription promoter; a DNA segment encoding a protein as described above; and a transcription terminator; whereby the cell expresses the protein encoded by the DNA segment; and recovering the expressed protein.

The invention also provides an oligonucleotide probe or primer comprising at least 14 contiguous nucleotides of a polynucleotide of SEQ ID NO:11 or a sequence complementary to SEQ ID NO:11.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 illustrates the three disulfide bond structure of the conserved β -defensin motif.

Figure 2 illustrates a multiple alignment of mature, processed human SAP-1 (see, for example, Bensch et al., FEBS Lett. 368(2): 331-5, 1995) and the zamp1 polypeptide of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

Prior to setting forth the invention in detail, it may be helpful to the understanding thereof to define the following terms.

The term "affinity tag" is used herein to denote a peptide segment that can be attached to a polypeptide to provide for purification of the polypeptide or provide sites for attachment of the polypeptide to a substrate. In principal, any peptide or protein for which an antibody or other specific binding agent is available can be used as an affinity tag. Affinity tags include a poly-histidine tract, protein A (Nilsson et al., *EMBO J.* 4:1075, 1985; Nilsson et al., *Methods Enzymol.* 198:3, 1991), glutathione S transferase (Smith and Johnson, *Gene* 67:31, 1988), substance P, FlagTM peptide (Hopp et al., *Biotechnology* 6:1204-1210, 1988; available from Eastman Kodak Co., New Haven, CT), streptavidin binding peptide, or other antigenic epitope or binding domain. See, in general Ford et al., *Protein Expression and Purification* 2: 95-107, 1991. DNAs encoding affinity tags are available from commercial suppliers (e.g., Pharmacia Biotech, Piscataway, NJ).

The term "allelic variant" denotes any of two or more alternative forms of a gene occupying the same chromosomal locus. Allelic variation arises naturally through mutation, and may result in phenotypic polymorphism within populations. Gene mutations can be silent (no change in the encoded polypeptide) or may encode polypeptides having altered amino acid sequence.

The term allelic variant is also used herein to denote a protein encoded by an allelic variant of a gene.

The terms "amino-terminal" and "carboxyl-terminal" are used herein to denote positions within polypeptides and proteins. Where the context allows, these terms are used with reference to a particular sequence or portion of a polypeptide or protein to denote proximity or relative position. For example, a certain sequence positioned carboxyl-terminal to a reference sequence within a protein is located proximal to the carboxyl terminus of the reference sequence, but is not necessarily at the carboxyl terminus of the complete protein.

The term "complement/anti-complement pair" denotes non-identical moieties that form a non-covalently associated, stable pair under appropriate conditions. For instance, biotin and avidin (or streptavidin) are prototypical members of a complement/anti-complement pair. Other exemplary complement/anti-complement pairs include receptor/ligand pairs, antibody/antigen (or hapten or epitope) pairs, sense/antisense polynucleotide pairs, and the like. Where subsequent dissociation of the complement/anti-complement pair is desirable, the complement/anti-complement pair preferably has a binding affinity of $<10^9 \text{ M}^{-1}$.

The term "complements of polynucleotide molecules" denotes polynucleotide molecules having a complementary base sequence and reverse orientation as compared to a reference sequence. For example, the sequence 5' ATGCACGGG 3' is complementary to 5' CCCGTGCAT 3'.

The term "degenerate nucleotide sequence" denotes a sequence of nucleotides that includes one or more degenerate codons (as compared to a reference polynucleotide molecule that encodes a polypeptide). Degenerate codons contain different triplets of

nucleotides, but encode the same amino acid residue (i.e., GAU and GAC triplets each encode Asp).

The term "expression vector" denotes a DNA molecule, linear or circular, that comprises a segment
5 encoding a polypeptide of interest operably linked to additional segments that provide for its transcription. Such additional segments may include promoter and terminator sequences, and may optionally include one or more origins of replication, one or more selectable
10 markers, an enhancer, a polyadenylation signal, and the like. Expression vectors are generally derived from plasmid or viral DNA, or may contain elements of both.

The term "isolated", when applied - to a polynucleotide molecule, denotes that the polynucleotide
15 has been removed from its natural genetic milieu and is thus free of other extraneous or unwanted coding sequences, and is in a form suitable for use within genetically engineered protein production systems. Such isolated molecules are those that are separated from their
20 natural environment and include cDNA and genomic clones. Isolated DNA molecules of the present invention are free of other genes with which they are ordinarily associated, but may include naturally occurring 5' and 3' untranslated regions such as promoters and terminators. The
25 identification of associated regions will be evident to one of ordinary skill in the art (see for example, Dynan and Tijan, Nature 316:774-78, 1985). When applied to a protein, the term "isolated" indicates that the protein is found in a condition other than its native environment,
30 such as apart from blood and animal tissue. In a preferred form, the isolated protein is substantially free of other proteins, particularly other proteins of animal origin. It is preferred to provide the protein in a highly purified form, i.e., greater than 95% pure, more
35 preferably greater than 99% pure.

The term "operably linked", when referring to DNA segments, denotes that the segments are arranged so

that they function in concert for their intended purposes, e.g. transcription initiates in the promoter and proceeds through the coding segment to the terminator.

5 The term "ortholog" denotes a polypeptide or protein obtained from one species that is the functional counterpart of a polypeptide or protein from a different species. Sequence differences among orthologs are the result of speciation.

10 The term "ortholog" denotes a polypeptide or protein obtained from one species that is the functional counterpart of a polypeptide or protein from a different species. Sequence differences among orthologs are the result of speciation.

15 The term "polynucleotide" denotes a single- or double-stranded polymer of deoxyribonucleotide or ribonucleotide bases read from the 5' to the 3' end. Polynucleotides include RNA and DNA, and may be isolated from natural sources, synthesized *in vitro*, or prepared from a combination of natural and synthetic molecules.

20 Sizes of polynucleotides are expressed as base pairs (abbreviated "bp"), nucleotides ("nt"), or kilobases ("kb"). Where the context allows, the latter two terms may describe polynucleotides that are single-stranded or double-stranded. When the term is applied to double-

25 stranded molecules it is used to denote overall length and will be understood to be equivalent to the term "base pairs". It will be recognized by those skilled in the art that the two strands of a double-stranded polynucleotide may differ slightly in length and that the ends thereof

30 may be staggered as a result of enzymatic cleavage; thus all nucleotides within a double-stranded polynucleotide molecule may not be paired. Such unpaired ends will in general not exceed 20 nt in length.

35 A "polypeptide" is a polymer of amino acid residues joined by peptide bonds, whether produced naturally or synthetically. Polypeptides of less than

about 10 amino acid residues are commonly referred to as "peptides".

The term "promoter" denotes a portion of a gene containing DNA sequences that provide for the binding of RNA polymerase and initiation of transcription. Promoter sequences are commonly, but not always, found in the 5' non-coding regions of genes.

The term "receptor" denotes a cell-associated protein that binds to a bioactive molecule (i.e., a ligand) and mediates the effect of the ligand on the cell. Membrane-bound receptors are characterized by a multi-domain structure comprising an extracellular ligand-binding domain and an intracellular effector domain that is typically involved in signal transduction. Binding of ligand to receptor results in a conformational change in the receptor that causes an interaction between the effector domain and other molecule(s) in the cell. This interaction in turn leads to an alteration in the metabolism of the cell. Metabolic events that are linked to receptor-ligand interactions include gene transcription, phosphorylation, dephosphorylation, increases in cyclic AMP production, mobilization of cellular calcium, mobilization of membrane lipids, cell adhesion, hydrolysis of inositol lipids and hydrolysis of phospholipids. Most nuclear receptors also exhibit a multi-domain structure, including an amino-terminal, transactivating domain, a DNA binding domain and a ligand binding domain. In general, receptors can be membrane bound, cytosolic or nuclear; monomeric (e.g., thyroid stimulating hormone receptor, beta-adrenergic receptor) or multimeric (e.g., PDGF receptor, growth hormone receptor, IL-3 receptor, GM-CSF receptor, G-CSF receptor, erythropoietin receptor and IL-6 receptor).

The term "secretory signal sequence" denotes a DNA sequence that encodes a polypeptide (a "secretory peptide") that, as a component of a larger polypeptide, directs the larger polypeptide through a secretory pathway

of a cell in which it is synthesized. The larger peptide is commonly cleaved to remove the secretory peptide during transit through the secretory pathway.

A "soluble receptor" is a receptor polypeptide that is not bound to a cell membrane. Soluble receptors are most commonly ligand-binding receptor polypeptides that lack transmembrane and cytoplasmic domains. Soluble receptors can comprise additional amino acid residues, such as affinity tags that provide for purification of the polypeptide or provide sites for attachment of the polypeptide to a substrate, or immunoglobulin constant region sequences. Many cell-surface receptors have naturally occurring, soluble counterparts that are produced by proteolysis or translated from alternatively spliced mRNAs. Receptor polypeptides are said to be substantially free of transmembrane and intracellular polypeptide segments when they lack sufficient portions of these segments to provide membrane anchoring or signal transduction, respectively.

Molecular weights and lengths of polymers determined by imprecise analytical methods (e.g., gel electrophoresis) will be understood to be approximate values. When such a value is expressed as "about" X or "approximately" X, the stated value of X will be understood to be accurate to $\pm 10\%$.

All references cited herein are incorporated by reference in their entirety.

The present invention is based in part upon the discovery of a novel DNA sequence that encodes a polypeptide having homology to proteins of the β -defensin family. That is, the zamp1 polypeptides of the present invention exhibit a conserved motif shown in SEQ ID NO: 3 and herein: C(X)₆C(X)₄C(X)₄GXC(X)₆CC wherein "(X)" is the number of preferably non-cysteine amino acid residues between specific amino acids. The cysteine position and spacing is characteristic of the β -defensin family. In addition, the QIG tripeptide motif embedded in the

conserved motif shown in SEQ ID NO: 3 occurs in several members of the β -defensin family (for example, SAP-1/hBD-2, BNBDs, TAP and the like). This motif is interpreted to indicate the presence of three disulfide bonds in the β -defensin structure. Those disulfide bonds are shown in Fig. 1. In addition, an intron sequence of approximately 900 base pairs is found in genomic DNA sequence encoding the zamp1 polypeptide. This intron sequence is inserted between the two guanine residues in the codon encoding the glycine residue at amino acid position 20 in SEQ ID NO: 10. Such intron placement, in the area between the signal sequence and the mature protein occurs in other members of the β -defensin family.

A standard Northern blot tissue distribution of the mRNA corresponding to this novel DNA revealed no expression. It thus appears that normal tissue levels of mRNA of zamp1 polypeptide are below the detection sensitivity of the Northern blot. Such an observation is consistent with the knowledge in the art regarding defensins, *i.e.*, that they are constitutively expressed at low levels but are highly inducible upon infection. Electronic analysis of tissue distribution based upon libraries where the sequence is found indicate that zamp1 polypeptide is expressed in bronchial epithelia.

The novel zamp1 polypeptides of the present invention were initially identified by querying an EST database for homologous sequences to the SAP-1 human defensin isolated from human psoriatic skin. A single EST sequence was discovered in a bronchial epithelium cDNA library and was predicted to be related to the β -defensin family. A second search based upon the β -defensin consensus motif also identified the EST. Thus, the consensus motif is found in the zamp1 polypeptide as well as in the SAP-1 protein; however, the remaining sequence of the two proteins is divergent, characterized by approximately 43% identity at the amino acid level. See, for example, the multiple alignment shown in Fig. 2.

The nucleotide sequence of the zampl polypeptide is described in SEQ ID NO: 1 and SEQ ID NO: 9, and its deduced amino acid sequence is described in SEQ ID NO: 2 and SEQ ID NO: 10, respectively. The zampl polypeptide, by sequence analysis, can be grouped with the two human β -defensins, hBD-1 and hBD-2 (SAP-1), but it is most closely sequence-related to hBD-2 and the bovine BNBDs and less similar to hBD-1.

Preliminary computer-aided model building efforts to construct a three-dimensional model structure for zampl polypeptide indicate that it is feasible to generate physically reasonable model structures using BNBD_12 (Zimmermann et al., Biochemistry 34(41): 13663-13671, 1995) as a template. Although there is relatively low sequence identity between these two peptides, their overall secondary structure is very similar. The most variability is observed in the loop regions, which is not alarming since the loop segments represent one of many possible conformations for each loop. Both structures are built primarily of an anti-parallel beta sheet core, four-stranded in the BNBD_12 model and three-stranded in the zampl polypeptide model. A turn formed between two of the beta strands in the BNBD_12 chain is also found in the zampl polypeptide model connecting two beta strands. The overall folding of BNBD_12 follows the pattern of beta strand/short beta strand/short beta strand/turn/beta strand. Folding of zampl polypeptide consists of beta strand/beta strand/turn/beta strand. These common structural elements are highly superimposable. Thus, the two polypeptides may well be involved in the same or similar biological processes.

Another aspect of the present invention includes zampl polypeptide fragments. Preferred fragments include the leader sequence, ranging from amino acid 1 (Ile) to amino acid 18 (Gly) or 20 (Gly) of SEQ ID NO: 2 and ranging from amino acid 1 (Met) to amino acid 20 (Gly) or 22 (Gly) of SEQ ID NO: 10. Such leader sequences may be

used to direct the secretion of other polypeptides. Such fragments of the present invention may be used as follows: the alternative secretion leader fragments are formed as fusion proteins with alternative proteins selected for secretion; plasmids bearing regulatory regions capable of directing the expression of the fusion protein are introduced into test cells; and secretion of the protein is monitored.

The present invention also provides fusion constructs incorporating the zampl polypeptide selected from the group consisting of: (a) polypeptide molecules comprising a sequence of amino acid residues as shown in SEQ ID NO:2 from amino acid residue 1 (Ile), 19 (His) or 21 (Gly) to amino acid residue 65 (Lys) or a sequence of amino acid residues as shown in SEQ ID NO: 10 from amino acid residue 1 (Met), 21 (His) or 23 (Gly) to amino acid residue 67 (Lys); or (b) mammalian species homologs or human paralogs of (a); at least the mature polypeptide region of another defensin molecule; and, optionally, a polypeptide linker there between. When defensin molecules having disparate spectrum of pathogens, fusion constructs containing the same are expected to exhibit a broader range of anti-microbial effectiveness. Polypeptide linkers are preferably employed if necessary to provide separation of component polypeptides of the fusion or to allow for flexibility of the fusion protein, thereby preserving the anti-microbial activity of each defensin component of the fusion protein. Those of ordinary skill in the art are capable of designing such linkers.

The highly conserved amino acids in the consensus domain of zampl polypeptide can be used as a tool to identify new family members. For instance, reverse transcription-polymerase chain reaction (RT-PCR) can be used to amplify sequences encoding the conserved motif from RNA obtained from a variety of tissue sources. More specifically, the following probes can be employed to identify other human or zampl-like β -defensins. A

preferred embodiment of this aspect of the present invention ranges between amino acid residues 31 and 61 of SEQ ID NO: 2 (corresponding to nucleotides 91-183 of SEQ ID NO: 1). In particular, highly degenerate primers
5 designed from the above sequences are useful for this purpose.

SEQ ID NO: 4 is a degenerate polynucleotide sequence that encompasses all polynucleotides that encode the zampl polypeptide of SEQ ID NO: 2 (amino acids 1-65).
10 SEQ ID NO: 11 is a degenerate polynucleotide sequence that encompasses all polynucleotides that encode the zampl polypeptide of SEQ ID NO: 10. Thus, zampl polypeptide-encoding polynucleotides ranging from nucleotide 1, 61 or 67 to nucleotide 195 or 213 of SEQ ID NO: 4 and ranging
15 from nucleotide 1, 61 or 67 to nucleotide 201 or 219 of SEQ ID NO: 11 are contemplated by the present invention. Also contemplated by the present invention are fragments and fusions as described above with respect to SEQ ID NO: 1 and SEQ ID NO: 10, which are formed from analogous
20 regions of SEQ ID NO: 4 and SEQ ID NO: 11. The symbols in SEQ ID NO: 4 are summarized in Table 1 below.

TABLE 1

5 The degenerate codons used in SEQ ID NO: 4 and SEQ ID NO: 11, encompassing all possible codons for a given amino acid, are set forth in Table 2 below.

TABLE 2

One of ordinary skill in the art will appreciate
 5 that some ambiguity is introduced in determining a
 degenerate codon, representative of all possible codons
 encoding each amino acid. For example, the degenerate
 codon for serine (WSN) can, in some circumstances, encode
 arginine (AGR), and the degenerate codon for arginine
 10 (MGN) can, in some circumstances, encode serine (AGY). A

similar relationship exists between codons encoding phenylalanine and leucine. Thus, some polynucleotides encompassed by the degenerate sequence may encode variant amino acid sequences, but one of ordinary skill in the art
5 can easily identify such variant sequences by reference to the amino acid sequence of SEQ ID NO: 2 and SEQ ID NO: 10. Variant sequences can be readily tested for functionality as described herein.

Within another aspect of the present invention
10 there is provided a pharmaceutical composition comprising purified zampl polypeptide in combination with a pharmaceutically acceptable vehicle. Such pharmaceutical compositions are used in the treatment of conditions associated with pathological microbes, including
15 bacterial, fungal and viral infections. Antibacterial applications of zampl polypeptide include situations where the pathogen has become resistant to standard treatments. For example, hospital sepsis is an increasing problem, since *Staphylococcus* strains have become resistant to
20 commonly used antibiotics.

In general, anti-microbial activity of zampl polypeptides, fragments, fusions, antibodies, agonists and antagonists can be evaluated by techniques that are known in the art. More specifically, anti-microbial activity
25 can be assayed by evaluating the sensitivity of microbial cell cultures to test agents and by evaluating the protective effect of test agents on infected mice. See, for example, Musiek et al., Antimicrob. Agents Chemother. 3: 40, 1973. Antiviral activity can also be assessed by
30 protection of mammalian cell cultures. Known techniques for evaluating anti-microbial activity include, for example, Barsum et al., Eur. Respir. J. 8(5): 709-14, 1995; Sandovsky-Losica et al., J. Med. Vet. Mycol (England) 28(4): 279-87, 1990; Mehentee et al., J. Gen.
35 Microbiol (England) 135 (Pt. 8): 2181-8, 1989; Segal and Savage, Journal of Medical and Veterinary Mycology 24: 477-479, 1986 and the like. Known assays specific for

anti-viral activity include, for example, those described by Daher et al., J. Virol. 60(3): 1068-74, 1986.

In addition, contract laboratories offer services in evaluating anti-microbial properties. For example, Panlabs, Inc. of Bothell, Washington offer in vitro or in vivo testing for bacteria, gram negative (*Enterobacter cloacae*, *Escherichia coli*, *Klebsiella pneumonia*, *Proteus vulgaris*, *Pseudomonas aeruginosa*, *Salmonella typhimurium* and *Serratia marcescens*), gram positive (*Bacillus subtilis*, *Brevibacterium ammoniagenes*, *Corynebacterium minutissimum*, *Micrococcus luteus*, *Mycobacterium ranae*, *Staphylococcus* strains and *Streptococcus* strains) and anaerobic organisms (*Actinomyces viscosus*, *Bacteroides fragilis*, *Clostridium sporogenes*, *Corynebacterium acnes*, *Helicobacter pylori* and *Porphyromonas gingivalis*), as well as for protozoa (*Trichomonas foetus*) and fungi (e.g., *Candida albicans*, *Epidermophyton floccosum*, *Exophiala jeanselmei*, *Microsporum* strains, *Trichophyton* strains and the like). Also, Molecular Probes of Oregon has commercially available fluorescence technology for use in bacteriology.

If desired, zampl polypeptide, fragment, fusion protein, agonist, antagonist or antibody performance in this regard can be compared to proteins known to be functional in this regard, such as proline-rich proteins, lysozyme, histatins, lactoperoxidase or the like. In addition, zampl polypeptide, fragment, fusion protein, antibody, agonist or antagonist may be evaluated in combination with one or more anti-microbial agents to identify synergistic effects.

The pharmaceutical compositions of the present invention may also be used when pro-inflammatory activity is desired. Applications for such pro-inflammatory activity include the treatment of chronic tissue damage, particularly in areas having a limited or damaged vascular system, e.g., damage in extremities associated with

diabetes. In contrast, antagonists to zampl polypeptides may be useful as anti-inflammatory agents.

5 Zampl polypeptide pharmaceutical compositions of the present invention may also be used in the treatment of conditions where stimulation of immune responsiveness is desired. Such conditions include the treatment of patients having incompetent immune systems, such as AIDs patients or individuals that have undergone chemotherapy, radiation treatment or the like.

10 Because zampl polypeptide was found in a bronchial epithelia library and cystic fibrosis is characterized by frequent microbial infection, pharmaceutical compositions containing zampl polypeptide are also contemplated for use in the treatment of lung
15 infections associated with cystic fibrosis. Also contemplated by the present invention are engineered zampl polypeptides that are characterized by decreased sensitivity to salt concentration. Decreased sensitivity to high salt concentration will preserve anti-microbial
20 activity of engineered zampl polypeptides in high salt environments, such as in the lung airways of patients suffering from cystic fibrosis. In this manner, pharmaceutical compositions containing engineered zampl polypeptides that are formulated for delivery to the lungs
25 can be used to treat lung infections associated with cystic fibrosis.

Radiation hybrid mapping is a somatic cell genetic technique developed for constructing high-resolution, contiguous maps of mammalian chromosomes (Cox
30 et al., Science 250:245-50, 1990). Partial or full knowledge of a gene's sequence allows one to design PCR primers suitable for use with chromosomal radiation hybrid mapping panels. Commercially available radiation hybrid mapping panels which cover the entire human genome, such
35 as the Stanford G3 RH Panel and the GeneBridge 4 RH Panel (Research Genetics, Inc., Huntsville, AL), are available. These panels enable rapid, PCR-based chromosomal

localizations and ordering of genes, sequence-tagged sites (STSs), and other nonpolymorphic and polymorphic markers within a region of interest. This includes establishing directly proportional physical distances between newly discovered genes of interest and previously mapped markers. The precise knowledge of a gene's position can be useful for a number of purposes, including: 1) determining if a sequence is part of an existing contig and obtaining additional surrounding genetic sequences in various forms, such as YACs, BACs or cDNA clones; 2) providing a possible candidate gene for an inheritable disease which shows linkage to the same chromosomal region; and 3) cross-referencing model organisms, such as mouse, which may aid in determining what function a particular gene might have.

The results showed that the *zamp1* gene maps 33.5 cR_3000 from the top of the human chromosome 8 linkage group on the WICGR radiation hybrid map. Proximal and distal framework markers were CHLC.GATA62D10 and WI-3823 (D8S1511), respectively. The use of surrounding markers positions the *zamp1* gene in the 8p23.3-p23.2 region on the integrated LDB chromosome 8 map (The Genetic Location Database, University of Southampton, WWW server: http://cedar.genetics.soton.ac.uk/public_html/).

Previously, human defensin genes of both hematopoietic (such as HD-1, as described by Sparkes et al., Genomics 5(2): 240-4, 1989) and epithelial (such as HD-5 and HD-6, as described by Bevins et al., Genomics 31(1): 95-106, 1996) origin are localized on the short arm of human chromosome 8 (8p23). Several defensin genes, cryptidins, have been mapped in the mouse genome and are found in a region of conserved synteny with human on mouse chromosome 8. See, for example, Ouellette et al., Genomics 5(2): 233-9, 1989. Recently, Liu et al., Genomics 43(3): 316-20, 1997, reported the mapping of the *hBD_1* gene to the same cluster of defensins on chromosome 8. These authors propose that α - and β -defensin genes

arose from a common ancestral gene prior to mammalian divergence. Thus, the localization of the zampl polypeptide-encoding gene to this region of chromosome 8 adds a second human β -defensin to the same chromosomal location as the human classic defensins and supports the hypothesis for the evolution of defensins.

The present invention also provides reagents which will find use in diagnostic applications. For example, the zampl gene, a probe comprising zampl DNA or RNA or a subsequence thereof can be used to determine if the zampl gene is present on chromosome 8 or if a mutation has occurred. Detectable chromosomal aberrations at the zampl gene locus include but are not limited to aneuploidy, gene copy number changes, insertions, deletions, restriction site changes and rearrangements. Such aberrations can be detected using polynucleotides of the present invention by employing molecular genetic techniques, such as restriction fragment length polymorphism (RFLP) analysis, short tandem repeat (STR) analysis employing PCR techniques, and other genetic linkage analysis techniques known in the art (Sambrook et al., *ibid.*; Ausubel, et. al., *ibid.*; Marian, *Chest*, 108: 255-265, 1995).

Another aspect of the present invention involves the detection of zampl polypeptides in cell culture or in a serum sample or tissue biopsy of a patient undergoing evaluation for SPG, Chediak-Higashi syndrome or other conditions characterized by an alteration in defensin concentration. Zampl polypeptides can be detected using immunoassay techniques and antibodies capable of recognizing a zampl polypeptide epitope. More specifically, the present invention contemplates methods for detecting zampl polypeptide comprising:

exposing a solution or sample or cell culture lysate or supernatant, possibly containing zampl polypeptide, to an antibody attached to a solid support,

wherein said antibody binds to a first epitope of a zampl polypeptide;

washing said immobilized antibody-polypeptide to remove unbound contaminants;

5 exposing the immobilized antibody-polypeptide to a second antibody directed to a second epitope of a zampl polypeptide, wherein the second antibody is associated with a detectable label; and

detecting the detectable label. Zampl
10 polypeptide concentration differing from that of controls may be indicative of SPG, Chediak-Higashi syndrome or other conditions characterized by an alteration in defensin concentration. In addition, expression of zampl may be monitored in cystic fibrosis patients as a
15 predictor of the onset of infectious crises. Also, high defensin, such as zampl polypeptide, levels have been associated with cytotoxic effects in lung, indicating that zampl polypeptide levels can be used to direct treatment for averting or addressing such cytotoxicity. For
20 example, antibodies directed to zampl polypeptide can be administered to inactivate the same in a treatment modality.

Within additional aspects of the invention there are provided antibodies or synthesized binding
25 proteins(e.g., those generated by phage display, *E. coli* Fab, and the like) that specifically bind to the zampl polypeptides described above. Such antibodies are useful for, among other uses as described herein, preparation of anti-idiotypic antibodies. Synthesized binding proteins
30 may be produced by phage display using commercially available kits, such as the Ph.D.TM Phage Display Peptide Library Kits available from New England Biolabs, Inc. (Beverly, Massachusetts). Phage display techniques are described, for example, in US Patent Nos. 5,223,409,
35 5,403,484 and 5,571,698.

An additional aspect of the present invention provides methods for identifying agonists or antagonists

of the zamp1 polypeptides disclosed above, which agonists or antagonists may have valuable properties as discussed further herein. Within one embodiment, there is provided a method of identifying zamp1 polypeptide agonists, comprising providing cells responsive thereto, culturing the cells in the presence of a test compound and comparing the cellular response with the cell cultured in the presence of the zamp1 polypeptide, and selecting the test compounds for which the cellular response is of the same type.

Within another embodiment, there is provided a method of identifying antagonists of zamp1 polypeptide, comprising providing cells responsive to a zamp1 polypeptide, culturing a first portion of the cells in the presence of zamp1 polypeptide, culturing a second portion of the cells in the presence of the zamp1 polypeptide and a test compound, and detecting a decrease in a cellular response of the second portion of the cells as compared to the first portion of the cells.

A further aspect of the invention provides a method of studying chemoattraction of monocytes in cell culture, comprising incubating monocytes in a culture medium comprising a zamp1 polypeptide, fragment, fusion protein, antibody, agonist or antagonist to study or evaluate monocyte chemoattraction. Such evaluation may be conducted using methods known in the art, such as those described by Territo et al. referenced above.

Melanocortin receptors are G-coupled protein receptors which activate adenylate cyclase and cause calcium flux. The agouti protein (which contains a 36 amino acid domain that is toxin-like) is thought to inhibit the binding of MSH-alpha to MC1 and MC4. In addition, the agouti protein is thought to be an antagonist of calcium channels, and certain toxins are believed to modulate ion flux. Experimental evidence has been generated, suggesting that defensins are capable of blocking calcium channels.

A further aspect of the invention provides a method of studying activity of the melanocortin family of receptors in cell culture, comprising incubating cells that endogenously bear such receptors (e.g., ACTH
5 receptors or the like) or cells that have been engineered to bear such receptors in a culture medium comprising a ligand or putative ligand and zamp1 polypeptide, fragment, fusion protein, antibody, agonist or antagonist to study or evaluate ligand or putative ligand binding and/or ion
10 flux regulation or modulation. Such evaluation may be conducted using methods known in the art, such as those described by Zhu et al. referenced above.

A further aspect of the invention provides a method of studying ion flux in cell culture, comprising
15 incubating cells that are capable of ion flux, such as calcium flux, sodium flux, potassium flux or the like, in a culture medium comprising zamp1 polypeptide, fragment, fusion protein, antibody, agonist or antagonist to study or evaluate ion flux regulation or modulation.

A further aspect of the invention provides a method of studying cytotoxic activity against mammalian cells, such as tumor cells, in cell culture, comprising incubating such cells in a culture medium comprising a
20 zamp1 polypeptide, fragment, fusion protein, antibody, agonist or antagonist at high test agent and low cell concentration to study or evaluate cytotoxic activity. Such evaluation may be conducted using methods known in the art, such as those described by Lichtenstein et al., Blood 68: 1407-10, 1986 and Sheu et al., Antimicrob.
25 Agents Chemother. 28: 626-9, 1993.

Another aspect of the present invention involves the use of zamp1 polypeptides, fragments, fusion proteins or agonists as cell culture reagents in in vitro studies of exogenous microorganism infection, such as bacterial,
35 viral or fungal infection. Such moieties may also be used in in vivo animal models of infection.

An additional aspect of the present invention is to study epithelial cell defensin induction in cell culture. In this aspect of the present invention, epithelial cells are cultured and exposed to pathogenic stimuli. Induction of zamp1 polypeptide production by the epithelial cells is then measured.

Within preferred embodiments of the invention the isolated polynucleotides will hybridize to similar sized regions of SEQ ID NO:2, SEQ ID NO:3, SEQ ID NO: 10, other probe sequences specifically set forth herein, or a sequence complementary thereto, under stringent conditions. In general, stringent conditions are selected to be about 5°C lower than the thermal melting point (T_m) for the specific sequence at a defined ionic strength and pH. The T_m is the temperature (under defined ionic strength and pH) at which 50% of the target sequence hybridizes to a perfectly matched probe. Typical stringent conditions are those in which the salt concentration is up to about 0.03 M at pH 7 and the temperature is at least about 60°C.

As previously noted, the isolated polynucleotides of the present invention include DNA and RNA. Methods for isolating DNA and RNA are well known in the art. It is generally preferred to isolate RNA from bronchial epithelium, although DNA can also be prepared using RNA from other tissues or isolated as genomic DNA. Total RNA can be prepared using guanidine HCl extraction followed by isolation by centrifugation in a CsCl gradient (Chirgwin et al., Biochemistry 18:52-94, 1979). Poly (A)⁺ RNA is prepared from total RNA using the method of Aviv and Leder (Proc. Natl. Acad. Sci. USA 69:1408-1412, 1972). Complementary DNA (cDNA) is prepared from poly(A)⁺ RNA using known methods. Polynucleotides encoding zamp1 polypeptides are then identified and isolated by, for example, hybridization or PCR.

The present invention further provides counterpart polypeptides and polynucleotides from other

species (orthologs). These species include, but are not limited to mammalian, avian, amphibian, reptile, fish, insect and other vertebrate and invertebrate species. Of particular interest are zamp1 polypeptides from other mammalian species, including murine, rat, porcine, ovine, bovine, canine, feline, equine and other primate proteins. Species homologs of the human proteins can be cloned using information and compositions provided by the present invention in combination with conventional cloning techniques. For example, a cDNA can be cloned using mRNA obtained from a tissue or cell type that expresses the protein. Suitable sources of mRNA can be identified by probing Northern blots with probes designed from the sequences disclosed herein. A library is then prepared from mRNA of a positive tissue or cell line. A zamp1 polypeptide-encoding cDNA can then be isolated by a variety of methods, such as by probing with a complete or partial human cDNA or with one or more sets of degenerate probes based on the disclosed sequences. A cDNA can also be cloned using the polymerase chain reaction, or PCR (Mullis, U.S. Patent 4,683,202), using primers designed from the sequences disclosed herein. Within an additional method, the cDNA library can be used to transform or transfect host cells, and expression of the cDNA of interest can be detected with an antibody to zamp1 polypeptide. Similar techniques can also be applied to the isolation of genomic clones.

Those skilled in the art will recognize that the sequences disclosed in SEQ ID NO:1, SEQ ID NO:2, SEQ ID NO:9 and SEQ ID NO:10 represent a single allele of the human zamp1 gene and polypeptide, and that allelic variation and alternative splicing are expected to occur. Allelic variants can be cloned by probing cDNA or genomic libraries from different individuals according to standard procedures. Allelic variants of the DNA sequence shown in SEQ ID NO:2 and SEQ ID NO:10, including those containing silent mutations and those in which mutations result in

amino acid sequence changes, are within the scope of the present invention.

The present invention also provides isolated zamp1 polypeptides that are substantially homologous to the polypeptides of SEQ ID NO:2 and SEQ ID NO:10 and their species homologs/ orthologs. The term "substantially homologous" is used herein to denote polypeptides having 50%, preferably 60%, more preferably at least 80%, sequence identity to the sequences shown in SEQ ID NO:2 or SEQ ID NO:10 or their orthologs or paralogs. Such polypeptides will more preferably be at least 90% identical, and most preferably 95% or more identical to SEQ ID NO:2 or SEQ ID NO:10 or its orthologs or paralogs. Percent sequence identity is determined by conventional methods. See, for example, Altschul et al., Bull. Math. Bio. 48: 603-616, 1986 and Henikoff and Henikoff, Proc. Natl. Acad. Sci. USA 89:10915-10919, 1992. Briefly, two amino acid sequences are aligned to optimize the alignment scores using a gap opening penalty of 10, a gap extension penalty of 1, and the "blosum 62" scoring matrix of Henikoff and Henikoff (ibid.) as shown in Table 3 (amino acids are indicated by the standard one-letter codes). The percent identity is then calculated as:

$$\frac{\text{Total number of identical matches}}{[\text{length of the longer sequence plus the number of gaps introduced into the longer sequence in order to align the two sequences}]} \times 100$$

Sequence identity of polynucleotide molecules is determined by similar methods using a ratio as disclosed above.

Substantially homologous proteins and polypeptides are characterized as having one or more amino acid substitutions, deletions or additions. These changes are preferably of a minor nature, that is conservative amino acid substitutions (see Table 4) and other substitutions that do not significantly affect the folding or activity of the protein or polypeptide; small deletions, typically of one to about 30 amino acids; and small amino- or carboxyl-terminal extensions, such as an amino-terminal methionine residue, a small linker peptide of up to about 20-25 residues, or a small extension that facilitates purification (an affinity tag), such as a poly-histidine tract, protein A (Nilsson et al., EMBO J. 4:1075, 1985; Nilsson et al., Methods Enzymol. 198:3, 1991), glutathione S transferase (Smith and Johnson, Gene 67:31, 1988), maltose binding protein (Kellerman and Ferenci, Methods Enzymol. 90:459-463, 1982; Guan et al., Gene 67:21-30, 1987), thioredoxin, ubiquitin, cellulose binding protein, T7 polymerase, or other antigenic epitope or binding domain. See, in general Ford et al., Protein Expression and Purification 2: 95-107, 1991. DNAs encoding affinity tags are available from commercial suppliers (e.g., Pharmacia Biotech, Piscataway, NJ; New England Biolabs, Beverly, MA). Polypeptides comprising affinity tags can further comprise a proteolytic cleavage site between the zamp1 polypeptide and the affinity tag. Preferred such sites include thrombin cleavage sites and factor Xa cleavage sites.

The proteins of the present invention can also comprise, in addition to the 20 standard amino acids, non-naturally occurring amino acid residues. Non-naturally occurring amino acids include, without limitation, trans-3-methylproline, 2,4-methanoproline, cis-4-hydroxyproline, trans-4-hydroxyproline, N-methyl-glycine, allo-threonine, methylthreonine, hydroxyethyl-cysteine, hydroxyethylhomocysteine, nitroglutamine, homoglutamine, 30 pipecolic acid, tert-leucine, norvaline, 2-azaphenylalanine, 3-azaphenylalanine, 4-azaphenyl-alanine, 4-fluorophenylalanine, 4-hydroxyproline, 6-N-methyl lysine, 2-aminoisobutyric acid, isovaline and α -methyl serine. Several methods are known in the art for incorporating non-naturally occurring amino acid residues into proteins. For 35 example, an *in vitro* system can be employed wherein nonsense mutations are suppressed using chemically

aminoacylated suppressor tRNAs. Methods for synthesizing amino acids and aminoacylating tRNA are known in the art. Transcription and translation of plasmids containing nonsense mutations are carried out in a cell free system comprising an *E. coli* S30 extract and commercially available enzymes and other reagents. Proteins are purified by chromatography. See, for example, Robertson et al., J. Am. Chem. Soc. 113:2722, 1991; Ellman et al., Meth. Enzymol. 202:301, 1991; Chung et al., Science 259:806-09, 1993; and Chung et al., Proc. Natl. Acad. Sci. USA 90:10145-49, 1993). In a second method, translation is carried out in *Xenopus* oocytes by microinjection of mutated mRNA and chemically aminoacylated suppressor -tRNAs (Turcatti et al., J. Biol. Chem. 271:19991-98, 1996). Within a third method, *E. coli* cells are cultured in the absence of a natural amino acid that is to be replaced (e.g., phenylalanine) and in the presence of the desired non-naturally occurring amino acid(s) (e.g., 2-azaphenylalanine, 3-azaphenylalanine, 4-azaphenylalanine, or 4-fluorophenylalanine). The non-naturally occurring amino acid is incorporated into the protein in place of its natural counterpart. See, Koide et al., Biochem. 33:7470-76, 1994. Naturally occurring amino acid residues can be converted to non-naturally occurring species by *in vitro* chemical modification. Chemical modification can be combined with site-directed mutagenesis to further expand the range of substitutions (Wynn and Richards, Protein Sci. 2:395-403, 1993).

A limited number of non-conservative amino acids, amino acids that are not encoded by the genetic code, non-naturally occurring amino acids, and unnatural amino acids may be substituted for zamp1 polypeptide amino acid residues. "Unnatural amino acids" have been modified after protein synthesis, and/or have a chemical structure in their side chain(s) different from that of the standard amino acids. Unnatural amino acids can be chemically synthesized, or preferably, are commercially available, and

include pipecolic acid, thiazolidine carboxylic acid, dehydroproline, 3- and 4-methylproline, and 3,3-dimethylproline.

Essential amino acids in the zamp1 polypeptides
5 of the present invention can be identified according to procedures known in the art, such as site-directed mutagenesis or alanine-scanning mutagenesis (Cunningham and Wells, Science 244: 1081-1085, 1989). In the latter technique, single alanine mutations are introduced at every
10 residue in the molecule, and the resultant mutant molecules are tested for biological activity (e.g., anti-microbial activity) to identify amino acid residues that are critical to the activity of the molecule. See also, Hilton et al., J. Biol. Chem. 271:4699-4708, 1996. Sites of ligand-
15 receptor or other biological interaction can also be determined by physical analysis of structure, as determined by such techniques as nuclear magnetic resonance, crystallography, electron diffraction or photoaffinity labeling, in conjunction with mutation of putative contact
20 site amino acids. See, for example, de Vos et al., Science 255:306-312, 1992; Smith et al., J. Mol. Biol. 224:899-904, 1992; Wlodaver et al., FEBS Lett. 309:59-64, 1992. The identities of essential amino acids can also be inferred from analysis of homologies with related β -defensins.

25 Multiple amino acid substitutions can be made and tested using known methods of mutagenesis and screening, such as those disclosed by Reidhaar-Olson and Sauer (Science 241:53-57, 1988) or Bowie and Sauer (Proc. Natl. Acad. Sci. USA 86:2152-2156, 1989). Briefly, these authors
30 disclose methods for simultaneously randomizing two or more positions in a polypeptide, selecting for functional polypeptide, and then sequencing the mutagenized polypeptides to determine the spectrum of allowable substitutions at each position. Other methods that can be
35 used include phage display (e.g., Lowman et al., Biochem. 30:10832-10837, 1991; Ladner et al., U.S. Patent No. 5,223,409; Huse, WIPO Publication WO 92/06204) and region-

directed mutagenesis (Derbyshire et al., Gene 46:145, 1986; Ner et al., DNA 7:127, 1988).

Variants of the disclosed *zamp1* DNA and polypeptide sequences can be generated through DNA shuffling as disclosed by Stemmer, Nature 370:389-91, 1994, Stemmer, Proc. Natl. Acad. Sci. USA 91:10747-51, 1994 and WIPO Publication WO 97/20078. Briefly, variant DNAs are generated by in vitro homologous recombination by random fragmentation of a parent DNA followed by reassembly using PCR, resulting in randomly introduced point mutations. This technique can be modified by using a family of parent DNAs, such as allelic variants or DNAs from different species, to introduce additional variability into the process. Selection or screening for the desired activity, followed by additional iterations of mutagenesis and assay provides for rapid "evolution" of sequences by selecting for desirable mutations while simultaneously selecting against detrimental changes.

Mutagenesis methods as disclosed above can be combined with high-throughput, automated screening methods to detect activity of cloned, mutagenized polypeptides in host cells. Mutagenized DNA molecules that encode active polypeptides (e.g., anti-microbial activity) can be recovered from the host cells and rapidly sequenced using modern equipment. These methods allow the rapid determination of the importance of individual amino acid residues in a polypeptide of interest, and can be applied to polypeptides of unknown structure.

Using the methods discussed above, one of ordinary skill in the art can identify and/or prepare a variety of polypeptides that are substantially homologous to residues 1 to 65 of SEQ ID NO: 2 or to residues 1 to 67 of SEQ ID NO: 10 or allelic variants thereof and retain the anti-microbial properties of the wild-type protein. Such polypeptides may include additional amino acids from affinity tags and the like. Such polypeptides may also

include additional polypeptide segments as generally disclosed above.

The polypeptides of the present invention, including full-length proteins, fragments thereof and fusion proteins, can be produced in genetically engineered host cells according to conventional techniques. However, host cells must be selected with some care as a result of the anti-microbial activity of the molecules of the present invention. For example, any cell culture-based system must be evaluated, because zamp1 polypeptides, fragments, fusion proteins, antibodies, agonists or antagonists may kill the host cell as a part of an anti-microbial function. Zamp1 polypeptides are of a small enough size to permit preparation by PCR or other protein chemistry techniques to avoid any potential host cell toxicity problems. Alternatively, native or engineered precursor proteins, prior to post-translational cleavage to yield the mature zamp1 polypeptide, are inactive, thereby limiting host cell cytotoxicity prior to lysosomal packaging. See, for example, Lehrer et al., Cell 64: 229-30, 1991. Thus, precursor proteins to zamp1 polypeptides may be produced in microbial cell culture.

Suitable host cells are those cell types that can be transformed or transfected with exogenous DNA and grown in culture, and include bacteria, fungal cells, and cultured higher eukaryotic cells. Eukaryotic cells, particularly cultured cells of multicellular organisms, are preferred. Techniques for manipulating cloned DNA molecules and introducing exogenous DNA into a variety of host cells are disclosed by Sambrook et al., Molecular Cloning: A Laboratory Manual, 2nd ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY, 1989, and Ausubel et al. (eds.), Current Protocols in Molecular Biology, John Wiley and Sons, Inc., NY, 1987.

In general, a DNA sequence encoding a zamp1 polypeptide of the present invention is operably linked to other genetic elements required for its expression,

generally including a transcription promoter and terminator within an expression vector. The vector will also commonly contain one or more selectable markers and one or more origins of replication, although those skilled in the art will recognize that within certain systems selectable markers may be provided on separate vectors, and replication of the exogenous DNA may be provided by integration into the host cell genome. Selection of promoters, terminators, selectable markers, vectors and other elements is a matter of routine design within the level of ordinary skill in the art. Many such elements are described in the literature and are available through commercial suppliers.

To direct a zampl polypeptide into the secretory pathway of a host cell, a secretory signal sequence (also known as a leader sequence, prepro sequence or pre sequence) is provided in the expression vector. The secretory signal sequence may be that of the zampl polypeptide, or may be derived from another secreted protein (e.g., t-PA) or synthesized *de novo*. The secretory signal sequence is joined to the zampl polypeptide-encoding DNA sequence in the correct reading frame. Secretory signal sequences are commonly positioned 5' to the DNA sequence encoding the polypeptide of interest, although certain signal sequences may be positioned elsewhere in the DNA sequence of interest (see, e.g., Welch et al., U.S. Patent No. 5,037,743; Holland et al., U.S. Patent No. 5,143,830).

Alternatively, the secretory signal sequence contained in the polypeptides of the present invention is used to direct other polypeptides into the secretory pathway. The present invention provides for such fusion polypeptides. A signal fusion polypeptide can be made wherein a secretory signal sequence derived from amino acid residues 1-18 or 12 of SEQ ID NO:2 or amino acid residues 1-20 or 22 of SEQ ID NO:10, is operably linked to another polypeptide using methods known in the art and disclosed

herein. The secretory signal sequence contained in the fusion polypeptides of the present invention is preferably fused amino-terminally to an additional peptide to direct the additional peptide into the secretory pathway. Such constructs have numerous applications known in the art. For example, these novel secretory signal sequence fusion constructs can direct the secretion of an active component of a normally non-secreted protein, such as a receptor. Such fusions may be used *in vivo* or *in vitro* to direct peptides through the secretory pathway.

Cultured mammalian cells are also preferred hosts within the present invention. Methods for introducing exogenous DNA into mammalian host cells include calcium phosphate-mediated transfection (Wigler et al., Cell 14:725, 1978; Corsaro and Pearson, Somatic Cell Genetics 7:603, 1981; Graham and Van der Eb, Virology 52:456, 1973), electroporation (Neumann et al., EMBO J. 1:841-845, 1982), DEAE-dextran mediated transfection (Ausubel et al., eds., Current Protocols in Molecular Biology, John Wiley and Sons, Inc., NY, 1987), liposome-mediated transfection (Hawley-Nelson et al., Focus 15:73, 1993; Ciccarone et al., Focus 15:80, 1993), and viral vectors (A. Miller and G. Rosman, BioTechniques 7:980-90, 1989; Q. Wang and M. Finer, Nature Med. 2:714-16, 1996). The production of recombinant polypeptides in cultured mammalian cells is disclosed, for example, by Levinson et al., U.S. Patent No. 4,713,339; Hagen et al., U.S. Patent No. 4,784,950; Palmiter et al., U.S. Patent No. 4,579,821; and Ringold, U.S. Patent No. 4,656,134. Preferred cultured mammalian cells include the COS-1 (ATCC No. CRL 1650), COS-7 (ATCC No. CRL 1651), BHK 570 (ATCC No. CRL 10314), 293 (ATCC No. CRL 1573; Graham et al., J. Gen. Virol. 36:59-72, 1977) and Chinese hamster ovary (e.g. CHO-K1; ATCC No. CCL 61) cell lines. Additional suitable cell lines are known in the art and available from public depositories such as the American Type Culture Collection, Rockville, Maryland. In general, strong transcription promoters are preferred, such as

promoters from SV-40 or cytomegalovirus. See, e.g., U.S. Patent No. 4,956,288. Other suitable promoters include those from metallothionein genes (U.S. Patent Nos. 4,579,821 and 4,601,978) and the adenovirus major late promoter.

Drug selection is generally used to select for cultured mammalian cells into which foreign DNA has been inserted. Such cells are commonly referred to as "transfectants". Cells that have been cultured in the presence of the selective agent and are able to pass the gene of interest to their progeny are referred to as "stable transfectants." A preferred selectable marker is a gene encoding resistance to the antibiotic neomycin. Selection is carried out in the presence of a neomycin-type drug, such as G-418 or the like. Selection systems may also be used to increase the expression level of the gene of interest, a process referred to as "amplification." Amplification is carried out by culturing transfectants in the presence of a low level of the selective agent and then increasing the amount of selective agent to select for cells that produce high levels of the products of the introduced genes. A preferred amplifiable selectable marker is dihydrofolate reductase, which confers resistance to methotrexate. Other drug resistance genes (e.g., hygromycin resistance, multi-drug resistance, puromycin acetyltransferase) can also be used. Alternative markers that introduce an altered phenotype, such as green fluorescent protein, or cell surface proteins such as CD4, CD8, Class I MHC, placental alkaline phosphatase may be used to sort transfected cells from untransfected cells by such means as FACS sorting or magnetic bead separation technology.

Other higher eukaryotic cells can also be used as hosts, including plant cells, insect cells and avian cells. The use of *Agrobacterium rhizogenes* as a vector for expressing genes in plant cells has been reviewed by Sinkar et al., J. Biosci. (Bangalore) 11:47-58, 1987.

Transformation of insect cells and production of foreign polypeptides therein is disclosed by Guarino et al., U.S. Patent No. 5,162,222 and WIPO publication WO 94/06463. Insect cells can be infected with recombinant baculovirus, commonly derived from *Autographa californica* nuclear polyhedrosis virus (AcNPV). DNA encoding the zampl polypeptide is inserted into the baculoviral genome in place of the AcNPV polyhedrin gene coding sequence by one of two methods. The first is the traditional method of homologous DNA recombination between wild-type AcNPV and a transfer vector containing the zampl flanked by AcNPV sequences. Suitable insect cells, e.g., SF9 cells, are infected with wild-type AcNPV and transfected with a transfer vector comprising a zampl polynucleotide operably linked to an AcNPV polyhedrin gene promoter, terminator, and flanking sequences. See, King and Possee, The Baculovirus Expression System: A Laboratory Guide, London, Chapman & Hall; O'Reilly et al., Baculovirus Expression Vectors: A Laboratory Manual, New York, Oxford University Press., 1994; and, Richardson, C. D., Ed., Baculovirus Expression Protocols. Methods in Molecular Biology, Totowa, NJ, Humana Press, 1995. Natural recombination within an insect cell will result in a recombinant baculovirus which contains zampl driven by the polyhedrin promoter. Recombinant viral stocks are made by methods commonly used in the art.

The second method of making recombinant baculovirus utilizes a transposon-based system described by Luckow (Luckow et al., J Virol. 67:4566-79, 1993). This system is sold in the Bac-to-Bac kit (Life Technologies, Rockville, MD). This system utilizes a transfer vector, pFastBac1™ (Life Technologies) containing a Tn7 transposon to move the DNA encoding the zampl polypeptide into a baculovirus genome maintained in *E. coli* as a large plasmid called a "bacmid." The pFastBac1™ transfer vector utilizes the AcNPV polyhedrin promoter to drive the expression of the gene of interest, in this case zampl. However,

pFastBac1™ can be modified to a considerable degree. The polyhedrin promoter can be removed and substituted with the baculovirus basic protein promoter (also known as Pcor, p6.9 or MP promoter) which is expressed earlier in the
5 baculovirus infection, and has been shown to be advantageous for expressing secreted proteins. See, Hill-Perkin and Possee, J. Gen. Virol. 71:971-6, 1990; Bonning. et al., J. Gen. Virol. 75:1551-6, 1994; and, Chazenbalk and Rapoport, J. Biol. Chem. 270:1543-9, 1995. In such
10 transfer vector constructs, a short or long version of the basic protein promoter can be used. Moreover, transfer vectors can be constructed which replace the native zamp1 secretory signal sequences with secretory signal sequences derived from insect proteins. For example, a secretory
15 signal sequence from Ecdysteroid Glucosyltransferase (EGT), honey bee Melittin (Invitrogen, Carlsbad, CA), or baculovirus gp67 (PharMingen, San Diego, CA) can be used in constructs to replace the native zamp1 secretory signal sequence. In addition, transfer vectors can include an in-
20 frame fusion with DNA encoding an epitope tag at the C- or N-terminus of the expressed zamp1 polypeptide, for example, a Glu-Glu epitope tag (Grussenmeyer et al., Proc. Natl. Acad. Sci. 82:7952-4, 1985). Using a technique known in the art, a transfer vector containing zamp1 is transformed
25 into *E. coli*, and screened for bacmids which contain an interrupted lacZ gene indicative of recombinant baculovirus. The bacmid DNA containing the recombinant baculovirus genome is isolated, using common techniques, and used to transfect *Spodoptera frugiperda* cells, e.g. Sf9
30 cells. Recombinant virus that expresses zamp1 is subsequently produced. Recombinant viral stocks are made by methods commonly used the art.

The recombinant virus is used to infect host cells, typically a cell line derived from the fall
35 armyworm, *Spodoptera frugiperda*. See, in general, Glick and Pasternak, Molecular Biotechnology: Principles and Applications of Recombinant DNA, ASM Press, Washington,

D.C., 1994. Another suitable cell line is the High FiveO™ cell line (Invitrogen) derived from *Trichoplusia ni* (U.S. Patent #5,300,435). Commercially available serum-free media are used to grow and maintain the cells. Suitable media are Sf900 II™ (Life Technologies) or ESF 921™ (Expression Systems) for the Sf9 cells; and Ex-cello405™ (JRH Biosciences, Lenexa, KS) or Express FiveO™ (Life Technologies) for the *T. ni* cells. The cells are grown up from an inoculation density of approximately $2-5 \times 10^5$ cells to a density of $1-2 \times 10^6$ cells at which time a recombinant viral stock is added at a multiplicity of infection (MOI) of 0.1 to 10, more typically near 3. The recombinant virus-infected cells typically produce the recombinant zamp1 polypeptide at 12-72 hours post-infection and secrete it with varying efficiency into the medium. The culture is usually harvested 48 hours post-infection. Centrifugation is used to separate the cells from the medium (supernatant). The supernatant containing the zamp1 polypeptide is filtered through micropore filters, usually 0.45 μm pore size. Procedures used are generally described in available laboratory manuals (King and Possee, *ibid.*; O'Reilly et al., *ibid.*; Richardson, *ibid.*). Subsequent purification of the zamp1 polypeptide from the supernatant can be achieved using methods described herein.

Fungal cells, including yeast cells, can also be used within the present invention. Yeast species of particular interest in this regard include *Saccharomyces cerevisiae*, *Pichia pastoris*, and *Pichia methanolica*. Methods for transforming *S. cerevisiae* cells with exogenous DNA and producing recombinant polypeptides therefrom are disclosed by, for example, Kawasaki, U.S. Patent No. 4,599,311; Kawasaki et al., U.S. Patent No. 4,931,373; Brake, U.S. Patent No. 4,870,008; Welch et al., U.S. Patent No. 5,037,743; and Murray et al., U.S. Patent No. 4,845,075. Transformed cells are selected by phenotype determined by the selectable marker, commonly drug resistance or the ability to grow in the absence of a

particular nutrient (e.g., leucine). A preferred vector system for use in *Saccharomyces cerevisiae* is the *POT1* vector system disclosed by Kawasaki et al. (U.S. Patent No. 4,931,373), which allows transformed cells to be selected
5 by growth in glucose-containing media. Suitable promoters and terminators for use in yeast include those from glycolytic enzyme genes (see, e.g., Kawasaki, U.S. Patent No. 4,599,311; Kingsman et al., U.S. Patent No. 4,615,974; and Bitter, U.S. Patent No. 4,977,092) and alcohol
10 dehydrogenase genes. See also U.S. Patents Nos. 4,990,446; 5,063,154; 5,139,936 and 4,661,454. Transformation systems for other yeasts, including *Hansenula polymorpha*, *Schizosaccharomyces pombe*, *Kluyveromyces lactis*, *Kluyveromyces fragilis*, *Ustilago maydis*, *Pichia pastoris*,
15 *Pichia methanolica*, *Pichia guilliermondii* and *Candida maltosa* are known in the art. See, for example, Gleeson et al., J. Gen. Microbiol. 132:3459-65, 1986 and Cregg, U.S. Patent No. 4,882,279. *Aspergillus* cells may be utilized according to the methods of McKnight et al., U.S. Patent
20 No. 4,935,349. Methods for transforming *Acremonium chrysogenum* are disclosed by Sumino et al., U.S. Patent No. 5,162,228. Methods for transforming *Neurospora* are disclosed by Lambowitz, U.S. Patent No. 4,486,533.

The use of *Pichia methanolica* as host for the
25 production of recombinant proteins is disclosed in WIPO Publications WO 97/17450, WO 97/17451, WO 98/02536, and WO 98/02565. DNA molecules for use in transforming *P. methanolica* will commonly be prepared as double-stranded, circular plasmids, which are preferably linearized prior to
30 transformation. For polypeptide production in *P. methanolica*, it is preferred that the promoter and terminator in the plasmid be that of a *P. methanolica* gene, such as a *P. methanolica* alcohol utilization gene (*AUG1* or *AUG2*). Other useful promoters include those of the
35 dihydroxyacetone synthase (*DHAS*), formate dehydrogenase (*FMD*), and catalase (*CAT*) genes. To facilitate integration of the DNA into the host chromosome, it is preferred to

have the entire expression segment of the plasmid flanked at both ends by host DNA sequences. A preferred selectable marker for use in *Pichia methanolica* is a *P. methanolica* ADE2 gene, which encodes phosphoribosyl-5-aminoimidazole
5 carboxylase (AIRC; EC 4.1.1.21), which allows *ade2* host cells to grow in the absence of adenine. For large-scale, industrial processes where it is desirable to minimize the use of methanol, it is preferred to use host cells in which both methanol utilization genes (*AUG1* and *AUG2*) are
10 deleted. For production of secreted proteins, host cells deficient in vacuolar protease genes (*PEP4* and *PRB1*) are preferred. Electroporation is used to facilitate the introduction of a plasmid containing DNA encoding a polypeptide of interest into *P. methanolica* cells. It is
15 preferred to transform *P. methanolica* cells by electroporation using an exponentially decaying, pulsed electric field having a field strength of from 2.5 to 4.5 kV/cm, preferably about 3.75 kV/cm, and a time constant (τ) of from 1 to 40 milliseconds, most preferably about 20
20 milliseconds.

Prokaryotic host cells, including strains of the bacteria *Escherichia coli*, *Bacillus* and other genera are also useful host cells within the present invention. Techniques for transforming these hosts and expressing
25 foreign DNA sequences cloned therein are well known in the art (see, e.g., Sambrook et al., *ibid.*). When expressing a *zamp1* polypeptide in bacteria such as *E. coli*, the polypeptide may be retained in the cytoplasm, typically as insoluble granules, or may be directed to the periplasmic
30 space by a bacterial secretion sequence. In the former case, the cells are lysed, and the granules are recovered and denatured using, for example, guanidine isothiocyanate or urea. The denatured polypeptide can then be refolded and dimerized by diluting the denaturant, such as by
35 dialysis against a solution of urea and a combination of reduced and oxidized glutathione, followed by dialysis against a buffered saline solution. In the latter case,

the polypeptide can be recovered from the periplasmic space in a soluble and functional form by disrupting the cells (by, for example, sonication or osmotic shock) to release the contents of the periplasmic space and recovering the protein, thereby obviating the need for denaturation and refolding.

Transformed or transfected host cells are cultured according to conventional procedures in a culture medium containing nutrients and other components required for the growth of the chosen host cells. A variety of suitable media, including defined media and complex media, are known in the art and generally include a carbon source, a nitrogen source, essential amino acids, vitamins and minerals. Media may also contain such components as growth factors or serum, as required. The growth medium will generally select for cells containing the exogenously added DNA by, for example, drug selection or deficiency in an essential nutrient which is complemented by the selectable marker carried on the expression vector or co-transfected into the host cell. *P. methanolica* cells are cultured in a medium comprising adequate sources of carbon, nitrogen and trace nutrients at a temperature of about 25°C to 35°C. Liquid cultures are provided with sufficient aeration by conventional means, such as shaking of small flasks or sparging of fermentors. A preferred culture medium for *P. methanolica* is YEPD (2% D-glucose, 2% Bacto™ Peptone (Difco Laboratories, Detroit, MI), 1% Bacto™ yeast extract (Difco Laboratories), 0.004% adenine and 0.006% L-leucine).

Expressed recombinant zampl polypeptides (or chimeric zampl polypeptides) can be purified using fractionation and/or conventional purification methods and media. Ammonium sulfate precipitation and acid or chaotrope extraction may be used for fractionation of samples. Exemplary purification steps may include hydroxyapatite, size exclusion, FPLC and reverse-phase high performance liquid chromatography. Suitable anion exchange media include derivatized dextrans, agarose, cellulose,

polyacrylamide, specialty silicas, and the like. PEI, DEAE, QAE and Q derivatives are preferred, with DEAE Fast-Flow Sepharose (Pharmacia, Piscataway, NJ) being particularly preferred. Exemplary chromatographic media include those media derivatized with phenyl, butyl, or octyl groups, such as Phenyl-Sepharose FF (Pharmacia), Toyopearl butyl 650 (Toso Haas, Montgomeryville, PA), Octyl-Sepharose (Pharmacia) and the like; or polyacrylic resins, such as Amberchrom CG 71 (Toso Haas) and the like.

5 include those media derivatized with phenyl, butyl, or octyl groups, such as Phenyl-Sepharose FF (Pharmacia), Toyopearl butyl 650 (Toso Haas, Montgomeryville, PA), Octyl-Sepharose (Pharmacia) and the like; or polyacrylic resins, such as Amberchrom CG 71 (Toso Haas) and the like.

10 Suitable solid supports include glass beads, silica-based resins, cellulosic resins, agarose beads, cross-linked agarose beads, polystyrene beads, cross-linked polyacrylamide resins and the like that are insoluble under the conditions in which they are to be used. These

15 supports may be modified with reactive groups that allow attachment of proteins by amino groups, carboxyl groups, sulfhydryl groups, hydroxyl groups and/or carbohydrate moieties. Examples of coupling chemistries include cyanogen bromide activation, N-hydroxysuccinimide

20 activation, epoxide activation, sulfhydryl activation, hydrazide activation, and carboxyl and amino derivatives for carbodiimide coupling chemistries. These and other solid media are well known and widely used in the art, and are available from commercial suppliers. Methods for

25 binding receptor polypeptides to support media are well known in the art. Selection of a particular method is a matter of routine design and is determined in part by the properties of the chosen support. See, for example, Affinity Chromatography: Principles & Methods, Pharmacia

30 LKB Biotechnology, Uppsala, Sweden, 1988.

The polypeptides of the present invention can be isolated by exploitation of their structural properties. For example, immobilized metal ion adsorption (IMAC) chromatography can be used to purify histidine-rich

35 proteins or proteins having a His-affinity tag. Briefly, a gel is first charged with divalent metal ions to form a chelate (Sulkowski, Trends in Biochem. 3:1-7, 1985).

Histidine-rich proteins will be adsorbed to this matrix with differing affinities, depending upon the metal ion used, and will be eluted by competitive elution, lowering the pH, or use of strong chelating agents. Other methods of purification include purification of glycosylated proteins by lectin affinity chromatography and ion exchange chromatography (Methods in Enzymol., Vol. 182, "Guide to Protein Purification", M. Deutscher, (ed.), Acad. Press, San Diego, 1990, pp.529-39). Within additional embodiments of the invention, a fusion of the polypeptide of interest and an affinity tag (e.g., maltose-binding protein, an immunoglobulin domain) may be constructed to facilitate purification.

Protein refolding (and optionally reoxidation) procedures may be advantageously used. It is preferred to purify the protein to >80% purity, more preferably to >90% purity, even more preferably >95%, and particularly preferred is a pharmaceutically pure state, that is greater than 99.9% pure with respect to contaminating macromolecules, particularly other proteins and nucleic acids, and free of infectious and pyrogenic agents. Preferably, a purified protein is substantially free of other proteins, particularly other proteins of animal origin.

Zampl polypeptides or fragments thereof may also be prepared through chemical synthesis. Zampl polypeptides may be monomers or multimers; glycosylated or non-glycosylated; pegylated or non-pegylated; amidated or non-amidated; sulfated or non-sulfated; and may or may not include an initial methionine amino acid residue. For example, zampl polypeptides can be synthesized by exclusive solid phase synthesis, partial solid phase methods, fragment condensation or classical solution synthesis. The polypeptides are preferably prepared by solid phase peptide synthesis, for example as described by Merrifield, J. Am. Chem. Soc. 85:2149, 1963. The synthesis is carried out with amino acids that are protected at the alpha-amino

terminus. Trifunctional amino acids with labile side-chains are also protected with suitable groups to prevent undesired chemical reactions from occurring during the assembly of the polypeptides. The alpha-amino protecting group is selectively removed to allow subsequent reaction to take place at the amino-terminus. The conditions for the removal of the alpha-amino protecting group do not remove the side-chain protecting groups.

The alpha-amino protecting groups are those known to be useful in the art of stepwise polypeptide synthesis. Included are acyl type protecting groups (e.g., formyl, trifluoroacetyl, acetyl), aryl type protecting groups (e.g., biotinyl), aromatic urethane type protecting groups [e.g., benzyloxycarbonyl (Cbz), substituted benzyloxycarbonyl and 9-fluorenylmethyloxy-carbonyl (Fmoc)], aliphatic urethane protecting groups [e.g., t-butyloxycarbonyl (tBoc), isopropyloxycarbonyl, cyclohexyloxycarbonyl] and alkyl type protecting groups (e.g., benzyl, triphenylmethyl). The preferred protecting groups are tBoc and Fmoc.

The side-chain protecting groups selected must remain intact during coupling and not be removed during the deprotection of the amino-terminus protecting group or during coupling conditions. The side-chain protecting groups must also be removable upon the completion of synthesis using reaction conditions that will not alter the finished polypeptide. In tBoc chemistry, the side-chain protecting groups for trifunctional amino acids are mostly benzyl based. In Fmoc chemistry, they are mostly tert-butyl or trityl based.

In tBoc chemistry, the preferred side-chain protecting groups are tosyl for arginine, cyclohexyl for aspartic acid, 4-methylbenzyl (and acetamidomethyl) for cysteine, benzyl for glutamic acid, serine and threonine, benzyloxymethyl (and dinitrophenyl) for histidine, 2-Cl-benzyloxycarbonyl for lysine, formyl for tryptophan and 2-bromobenzyl for tyrosine. In Fmoc chemistry, the preferred

side-chain protecting groups are 2,2,5,7,8-pentamethylchroman-6-sulfonyl (Pmc) or 2,2,4,6,7-pentamethyldihydrobenzofuran-5-sulfonyl (Pbf) for arginine, trityl for asparagine, cysteine, glutamine and histidine, 5 tert-butyl for aspartic acid, glutamic acid, serine, threonine and tyrosine, tBoc for lysine and tryptophan.

For the synthesis of phosphopeptides, either direct or post-assembly incorporation of the phosphate group is used. In the direct incorporation strategy, the 10 phosphate group on serine, threonine or tyrosine may be protected by methyl, benzyl, or tert-butyl in Fmoc chemistry or by methyl, benzyl or phenyl in tBoc chemistry. Direct incorporation of phosphotyrosine without phosphate protection can also be used in Fmoc chemistry. In the post- 15 assembly incorporation strategy, the unprotected hydroxyl groups of serine, threonine or tyrosine are derivatized on solid phase with di-tert-butyl-, dibenzyl- or dimethyl-N,N'-diisopropyl-phosphoramidite and then oxidized by tert-butylhydro-peroxide.

20 Solid phase synthesis is usually carried out from the carboxyl-terminus by coupling the alpha-amino protected (side-chain protected) amino acid to a suitable solid support. An ester linkage is formed when the attachment is made to a chloromethyl, chlorotrityl or hydroxymethyl 25 resin, and the resulting polypeptide will have a free carboxyl group at the C-terminus. Alternatively, when an amide resin such as benzhydrylamine or p-methylbenzhydrylamine resin (for tBoc chemistry) and Rink amide or PAL resin (for Fmoc chemistry) are used, an amide 30 bond is formed and the resulting polypeptide will have a carboxamide group at the C-terminus. These resins, whether polystyrene- or polyamide-based or polyethyleneglycol-grafted, with or without a handle or linker, with or without the first amino acid attached, are commercially 35 available, and their preparations have been described by Stewart et al., "Solid Phase Peptide Synthesis" (2nd Edition), (Pierce Chemical Co., Rockford, IL, 1984) and

Bayer and Rapp, Chem. Pept. Prot. 3:3, 1986; and Atherton et al., Solid Phase Peptide Synthesis: A Practical Approach, IRL Press, Oxford, 1989.

The C-terminal amino acid, protected at the side chain if necessary, and at the alpha-amino group, is attached to a hydroxymethyl resin using various activating agents including dicyclohexylcarbodiimide (DCC), N,N'-diisopropylcarbodiimide (DIPCDI) and carbonyldiimidazole (CDI). It can be attached to chloromethyl or chlorotrityl resin directly in its cesium tetramethylammonium salt form or in the presence of triethylamine (TEA) or diisopropylethylamine (DIEA). First amino acid attachment to an amide resin is the same as amide bond formation during coupling reactions.

Following the attachment to the resin support, the alpha-amino protecting group is removed using various reagents depending on the protecting chemistry (e.g., tBoc, Fmoc). The extent of Fmoc removal can be monitored at 300-320 nm or by a conductivity cell. After removal of the alpha-amino protecting group, the remaining protected amino acids are coupled stepwise in the required order to obtain the desired sequence.

Various activating agents can be used for the coupling reactions including DCC, DIPCDI, 2-chloro-1,3-dimethylimidium hexafluorophosphate (CIP), benzotriazol-1-yl-oxy-tris-(dimethylamino)-phosphonium hexafluorophosphate (BOP) and its pyrrolidine analog (PyBOP), bromo-tris-pyrrolidino-phosphonium hexafluorophosphate (PyBrOP), O-(benzotriazol-1-yl)-1,1,3,3-tetramethyl-uronium hexafluorophosphate (HBTU) and its tetrafluoroborate analog (TBTU) or its pyrrolidine analog (HBPYU), O-(7-azabenzotriazol-1-yl)-1,1,3,3-tetramethyl-uronium hexafluorophosphate (HATU) and its tetrafluoroborate analog (TATU) or its pyrrolidine analog (HAPYU). The most common catalytic additives used in coupling reactions include 4-dimethylaminopyridine (DMAP), 3-hydroxy-3,4-dihydro-4-oxo-1,2,3-benzotriazine (HODhbt), N-hydroxybenzotriazole (HOBt)

and 1-hydroxy-7-azabenzotriazole (HOAt). Each protected amino acid is used in excess (>2.0 equivalents), and the couplings are usually carried out in N-methylpyrrolidone (NMP) or in DMF, CH₂Cl₂ or mixtures thereof. The extent of
5 completion of the coupling reaction can be monitored at each stage, e.g., by the ninhydrin reaction as described by Kaiser et al., Anal. Biochem. 34:595, 1970.

After the entire assembly of the desired peptide, the peptide-resin is cleaved with a reagent with proper
10 scavengers. The Fmoc peptides are usually cleaved and deprotected by TFA with scavengers (e.g., H₂O, ethanedithiol, phenol and thioanisole). The tBoc peptides are usually cleaved and deprotected with liquid HF for 1-2 hours at -5 to 0° C, which cleaves the polypeptide from the
15 resin and removes most of the side-chain protecting groups. Scavengers such as anisole, dimethylsulfide and p-thiocresol are usually used with the liquid HF to prevent cations formed during the cleavage from alkylating and acylating the amino acid residues present in the
20 polypeptide. The formyl group of tryptophan and the dinitrophenyl group of histidine need to be removed, respectively by piperidine and thiophenyl in DMF prior to the HF cleavage. The acetamidomethyl group of cysteine can be removed by mercury(II)acetate and alternatively by
25 iodine, thallium(III) trifluoroacetate or silver tetrafluoroborate which simultaneously oxidize cysteine to cystine. Other strong acids used for tBoc peptide cleavage and deprotection include trifluoromethanesulfonic acid (TFMSA) and trimethylsilyltrifluoroacetate (TMSOTf).

30 A zempl polypeptide ligand-binding polypeptide can also be used for purification of ligand. The polypeptide is immobilized on a solid support, such as beads of agarose, cross-linked agarose, glass, cellulosic resins, silica-based resins, polystyrene, cross-linked
35 polyacrylamide, or like materials that are stable under the conditions of use. Methods for linking polypeptides to solid supports are known in the art, and include amine

chemistry, cyanogen bromide activation, N-hydroxysuccinimide activation, epoxide activation, sulfhydryl activation, and hydrazide activation. The resulting medium will generally be configured in the form of a column, and fluids containing ligand are passed through the column one or more times to allow ligand to bind to the receptor polypeptide. The ligand is then eluted using changes in salt concentration, chaotropic agents (guanidine HCl), or pH to disrupt ligand-receptor binding.

An assay system that uses a ligand-binding receptor (or an antibody, one member of a complement/anti-complement pair) or a binding fragment thereof, and a commercially available biosensor instrument (BIAcore™, Pharmacia Biosensor, Piscataway, NJ) may be advantageously employed. Such receptor, antibody, member of a complement/anti-complement pair or fragment is immobilized onto the surface of a receptor chip. Use of this instrument is disclosed by Karlsson, J. Immunol. Methods 145:229-40, 1991 and Cunningham and Wells, J. Mol. Biol. 234:554-63, 1993. A receptor, antibody, member or fragment is covalently attached, using amine or sulfhydryl chemistry, to dextran fibers that are attached to gold film within the flow cell. A test sample is passed through the cell. If a ligand, epitope, or opposite member of the complement/anti-complement pair is present in the sample, it will bind to the immobilized receptor, antibody or member, respectively, causing a change in the refractive index of the medium, which is detected as a change in surface plasmon resonance of the gold film. This system allows the determination of on- and off-rates, from which binding affinity can be calculated, and assessment of stoichiometry of binding.

Ligand-binding receptor polypeptides can also be used within other assay systems known in the art. Such systems include Scatchard analysis for determination of binding affinity (see Scatchard, Ann. NY Acad. Sci. 51:

660-72, 1949) and calorimetric assays (Cunningham et al., Science 253:545-48, 1991; Cunningham et al., Science 245:821-25, 1991).

Zampl polypeptides can also be used to prepare
5 antibodies that specifically bind to zampl polypeptide
epitopes, peptides or polypeptides. Methods for preparing
polyclonal and monoclonal antibodies are well known in the
art (see, for example, Sambrook et al., Molecular Cloning:
A Laboratory Manual, Second Edition, Cold Spring Harbor,
10 NY, 1989; and Hurrell, J. G. R., Ed., Monoclonal Hybridoma
Antibodies: Techniques and Applications, CRC Press, Inc.,
Boca Raton, FL, 1982). As would be evident to one of
ordinary skill in the art, polyclonal antibodies can be
generated from a variety of warm-blooded animals, such as
15 horses, cows, goats, sheep, dogs, chickens, rabbits, mice,
and rats.

The immunogenicity of a zampl polypeptide may be
increased through the use of an adjuvant, such as alum
(aluminum hydroxide) or Freund's complete or incomplete
20 adjuvant. Polypeptides useful for immunization also
include fusion polypeptides, such as fusions of zampl
polypeptide or a portion thereof with an immunoglobulin
polypeptide or with maltose binding protein. The
polypeptide immunogen may be a full-length molecule or a
25 portion thereof. If the polypeptide portion is "haptent-
like", such portion may be advantageously joined or linked
to a macromolecular carrier (such as keyhole limpet
hemocyanin (KLH), bovine serum albumin (BSA) or tetanus
toxoid) for immunization.

30 As used herein, the term "antibodies" includes
polyclonal antibodies, affinity-purified polyclonal
antibodies, monoclonal antibodies, and antigen-binding
fragments, such as F(ab')₂ and Fab proteolytic fragments.
Genetically engineered intact antibodies or fragments, such
35 as chimeric antibodies, Fv fragments, single chain
antibodies and the like, as well as synthetic antigen-
binding peptides and polypeptides, are also included. Non-

human antibodies may be humanized by grafting only non-human CDRs onto human framework and constant regions, or by incorporating the entire non-human variable domains (optionally "cloaking" them with a human-like surface by replacement of exposed residues, wherein the result is a "veneered" antibody). In some instances, humanized antibodies may retain non-human residues within the human variable region framework domains to enhance proper binding characteristics. Through humanizing antibodies, biological half-life may be increased, and the potential for adverse immune reactions upon administration to humans is reduced. Alternative techniques for generating or selecting antibodies useful herein include *in vitro* exposure of lymphocytes to zamp1 protein or peptide, and selection of antibody display libraries in phage or similar vectors (for instance, through use of immobilized or labeled zamp1 protein or peptide).

Antibodies are defined to be specifically binding if: 1) they exhibit a threshold level of binding activity, and/or 2) they do not significantly cross-react with related polypeptide molecules. First, antibodies herein specifically bind if they bind to a zamp1 polypeptide, peptide or epitope with a binding affinity (K_a) of 10^6 mol^{-1} or greater, preferably 10^7 mol^{-1} or greater, more preferably 10^8 mol^{-1} or greater, and most preferably 10^9 mol^{-1} or greater. The binding affinity of an antibody can be readily determined by one of ordinary skill in the art, for example, by Scatchard analysis (G. Scatchard, Ann. NY Acad. Sci. 51: 660-72, 1949).

Second, antibodies specifically bind if they do not significantly cross-react with related polypeptides. Antibodies do not significantly cross-react with related polypeptide molecules, for example, if they detect human zamp1 polypeptide, but not known related polypeptides using a standard Western blot analysis (Ausubel et al., *ibid.*). Examples of known related polypeptides are orthologs, that is, proteins from the same species that are members of a

protein family, such as other known human β -defensins (e.g., hBD-1 and hBD-2), mutant human β -defensins, and non-human β -defensins.

Moreover, antibodies may be "screened against" known related polypeptides to isolate a population that specifically binds to the inventive polypeptides. For example, antibodies raised to human zamp1 polypeptide are adsorbed with related polypeptides adhered to an insoluble matrix; antibodies specific to human zamp1 polypeptide will flow through the matrix under the proper buffer conditions. Such screening allows isolation of polyclonal and monoclonal antibodies non-crossreactive to closely related polypeptides (see, *Antibodies: A Laboratory Manual*, Harlow and Lane (eds.), Cold Spring Harbor Laboratory Press, 1988; *Current Protocols in Immunology*, Cooligan et al. (eds.), National Institutes of Health, John Wiley and Sons, Inc., 1995). Screening and isolation of specific antibodies is well known in the art (see, *Fundamental Immunology*, Paul (ed.), Raven Press, 1993; Getzoff et al., *Adv. Immunol.* 43:1-98, 1988; *Monoclonal Antibodies: Principles and Practice*, Goding, J.W. (eds.), Academic Press Ltd., 1996; Benjamin et al., *Ann. Rev. Immunol.* 2:67-101, 1984).

A variety of assays known to those skilled in the art can be utilized to detect antibodies which specifically bind to zamp1 proteins or peptides. Exemplary assays are described in detail in *Antibodies: A Laboratory Manual*, Harlow and Lane (Eds.), Cold Spring Harbor Laboratory Press, 1988. Representative examples of such assays include: concurrent immunoelectrophoresis, radioimmunoassay, radioimmuno-precipitation, enzyme-linked immunosorbent assay (ELISA), dot blot or Western blot assay, inhibition or competition assay, and sandwich assay. In addition, antibodies can be screened for binding to wild-type versus mutant zamp1 protein or peptide.

Antibodies to zamp1 polypeptides may be used for tagging cells that express zamp1 polypeptides; for isolating zamp1 polypeptides by affinity purification; for

diagnostic assays for determining circulating levels of zampl polypeptides; for detecting or quantitating soluble zampl polypeptide as a marker of underlying pathology or disease; in analytical methods employing FACS; for
5 screening expression libraries; for generating anti-idiotypic antibodies; and as neutralizing antibodies or as antagonists to block anti-microbial activity *in vitro* and *in vivo*.

For pharmaceutical use, the proteins of the
10 present invention are formulated for topical, inhalant or parenteral, particularly intravenous or subcutaneous, delivery according to conventional methods. Intravenous administration will be by bolus injection or infusion over a typical period of one to several hours. In general,
15 pharmaceutical formulations will include a zampl protein in combination with a pharmaceutically acceptable vehicle, such as saline, buffered saline, 5% dextrose in water or the like. Formulations may further include one or more excipients, preservatives, solubilizers, buffering agents,
20 albumin to prevent protein loss on vial surfaces, etc. Methods of formulation are well known in the art and are disclosed, for example, in Remington: The Science and Practice of Pharmacy, Gennaro, ed., Mack Publishing Co., Easton, PA, 19th ed., 1995. Therapeutic doses will
25 generally determined by the clinician according to accepted standards, taking into account the nature and severity of the condition to be treated, patient traits, etc. Determination of dose is within the level of ordinary skill in the art. The proteins may be administered for acute
30 treatment, over one week or less, often over a period of one to three days or may be used in chronic treatment, over several months or years.

The invention is further illustrated by the following non-limiting examples.

Example 1
Extension of EST Sequence

The novel zampl polypeptides of the present invention were initially identified by querying an EST database for homologous sequences to the SAP-1 human defensin isolated from human psoriatic skin. A single EST sequence was discovered in a bronchial epithelium cDNA library and was predicted to be related to the β -defensin family. A second search based upon the β -defensin consensus motif also identified the EST.

To identify the corresponding cDNA, a clone containing the EST was sought, but was not located. Oligonucleotides ZC14741 (SEQ ID NO: 5), ZC14740 (SEQ ID NO: 6) were used in a PCR reaction to isolate the zampl polypeptide-encoding sequence from human genomic DNA. Reaction conditions were 94°C for 1 minute and 30 seconds, followed by 35 cycles of 94°C for 10 seconds, 58°C for 20 seconds and 72°C for 20 seconds, followed by 72°C for ten minutes. As a template, 100 ng of human genomic DNA was used, and Clontech Advantage PCR mix (Clontech, Palo Alto, California) was used as the polymerase mixture. The resulting 113 bp fragment was then purified on a 3.2% NuSieve (FMC Bioproducts, Rockland, ME) gel using a QiaexII Gel Extraction Kit (Qiagen, Inc., Chatsworth, California) according to the manufacturer's directions. The purified material was used as a template for sequencing. The template was sequenced on an ABIPRISM™ model 377 DNA sequencer (Perkin-Elmer Cetus, Norwalk, Ct.) using the ABI PRISM™ Dye Terminator Cycle Sequencing Ready Reaction Kit (Perkin-Elmer Corp.) according to manufacturer's instructions. Oligonucleotides ZC14741 (SEQ ID NO: 5), ZC14740 (SEQ ID NO: 6) were used as primers for sequencing the clone. Sequencing reactions were carried out in a Hybaid OmniGene Temperature Cycling System (National Labnet Co., Woodbridge, NY). SEQUENCHER™ 3.1 sequence analysis software (Gene Codes Corporation, Ann Arbor, MI) was used

for data analysis. The resulting 113 bp sequence is disclosed in SEQ ID NO: 1. Comparison of the originally derived EST sequence with the sequence represented in SEQ ID NO: 1 showed that there were 2 base pair differences which resulted in 1 amino acid difference between the deduced amino acid sequences. Note that one of the base pair differences were from unknown "N" residues in the EST sequence to known residues in SEQ ID NO: 1.

Generally, one or a combination of several techniques could be used to obtain the full length sequence of the *zamp1* polypeptide-encoding polynucleotide. First, if one or more additional ESTs are identified that contig to the clone sequenced above, clones corresponding to such ESTs can be ordered and sequenced as described above and spliced together with the original sequence to form the full length sequence. If a small portion of the full length sequence is absent, 5' RACE reactions can be done, and the resulting fragments can be sequenced as described above and spliced together with the original sequence to form the full length sequence. Also, one or more cDNA libraries can be probed with all or a portion of SEQ ID NO: 1 to identify a putative full-length clone. Such a full length clone can be sequenced as described above.

25

Example 2 Tissue Distribution

Northerns were performed using Human Multiple Tissue Blots from Clontech (Palo Alto, CA). An approximately 113 bp DNA probe, based directly on the identified EST, was generated using PCR techniques, specifically a 35 cycle reaction with an annealing temperature of 58°C using Clontech Advantage KlenTaq Polymerase mix (Clontech, Palo Alto, California). The DNA probe was radioactively labeled with ³²P using REDIPRIME® DNA labeling system (Amersham, Arlington Heights, Illinois) according to the manufacturer's specifications. The probe

The zamp1 gene was mapped to chromosome 8 using the commercially available "GeneBridge 4 Radiation Hybrid Panel" (Research Genetics, Inc., Huntsville, AL). The GeneBridge 4 Radiation Hybrid Panel contains PCRable DNAs from each of 93 radiation hybrid clones, plus two control DNAs (the HFL donor and the A23 recipient). A publicly available WWW server (<http://www-genome.wi.mit.edu/cgi-bin/contig/rhmapper.pl>) allows mapping relative to the Whitehead Institute/MIT Center for Genome Research's radiation hybrid map of the human genome (the "WICGR" radiation hybrid map) which was constructed with the GeneBridge 4 Radiation Hybrid Panel.

3NSDOCID: <WO___9913080A1 | >

(SEQ ID NO: 8), 2 μ l "RediLoad" (Research Genetics, Inc., Huntsville, AL), 0.4 μ l 50X Advantage KlenTaq Polymerase Mix (Clontech Laboratories, Inc.), 25 ng of DNA from an individual hybrid clone or control and x μ l ddH₂O for a total volume of 20 μ l. The reactions were overlaid with an equal amount of mineral oil and sealed. The PCR cyclor conditions were as follows: an initial 1 cycle 5 minute denaturation at 95°C, 35 cycles of a 1 minute denaturation at 95°C, 1 minute annealing at 52°C and 1.5 minute extension at 72°C, followed by a final 1 cycle extension of 7 minutes at 72°C. The reactions were separated by electrophoresis on a 2% agarose gel (Life Technologies, Gaithersburg, MD).

The results showed that the zamp1 gene maps 33.5 cR_3000 from the top of the human chromosome 8 linkage group on the WICGR radiation hybrid map. Proximal and distal framework markers were CHLC.GATA62D10 and WI-3823 (D8S1511), respectively. The use of surrounding markers positions the zamp1 gene in the 8p23.3-p23.2 region on the integrated LDB chromosome 8 map (The Genetic Location Database, University of Southampton, WWW server: http://cedar.genetics.soton.ac.uk/public_html/).

Example 4

Identification of DNA Encoding Full Length Zamp1 Polypeptide and Sequencing Thereof

The 5' end of zamp1 coding sequence was obtained by PCR using GenomeWalker® reagents (Clontech) in combination with a zamp1 polypeptide-specific antisense primer ZC15591 (SEQ ID NO: 12) and then conducting nested PCR with ZC15589 (SEQ ID NO: 13), according to manufacturer's instructions, with the exception that 64°C was used in the primary reaction instead of the suggested 67°C. PCR products were run on a 2% agarose gel (Gibco), and gel purified using Qiaex II reagents (Qiagen) according to manufacturer's instructions. Products were sequenced using ZC15589 (SEQ ID NO: 13) as a sequencing primer,

revealing the extension of zampl polypeptide-encoding to a putative initiation methionine (nucleotides 1-201 or 1-219 of SEQ ID NO:9) and about 250 base pairs of 5' untranslated sequence.

5

Example 5
Synthesis of Zampl

10 A 45 amino acid residue zampl peptide (residues 23 to 67 of SEQ ID NO:2) was synthesized by solid phase peptide synthesis using a model 431A Peptide Synthesizer (Applied Biosystems/Perkin Elmer, Foster City, CA). Fmoc-Lysine(Boc) resin (0.52 mmol/g; Anaspec Inc., San Jose, CA)
15 was used as the initial support resin. 1 mmol Amino acid cartridges (Anaspec Inc., San Jose, CA and Applied Biosystems/Perkin Elmer, Foster City, CA) were used for synthesis.
20 2-(1-H-benzotriazol-1-yl)-1,1,3,3-tetramethyuroniumhexafluorophosphate (HBTU), 1-Hydroxy-benzotriazole (HOBt), 2 M N,N-Diisopropylethylamine, N-Methylpyrrolidone, Dichloromethane (all from Applied Biosystems/Perkin Elmer, Foster City, CA), along with piperidine (Aldrich Chemical Co., St. Louis, MO) and 0.5 M acetic anhydride capping solution (Advanced ChemTech,
25 Louisville, KY), were used as synthesis reagents.

 The Peptide Companion software (Peptides International, Louisville, KY) was used to help predict the aggregation potential for the synthesis for zampl. Synthesis was performed using both single and double
30 coupling cycles. Also, acetylation was used where difficult couplings were predicted.

 The peptide was cleaved from the solid phase by the standard TFA cleavage procedure (according to Peptide Cleavage manual, Applied Biosystems/Perkin Elmer).
35 Purification of the peptide was done by RP-HPLC using a C18, 52mm x 250mm, preparative column (Vydac, Hesperia, CA). Fractions from the column were collected and analyzed for the correct mass by electrospray mass spectrometry; the

purity was analyzed by analytical RP-HPLC, using a C18, 4.6mm x 250mm column (Vydac, Hesperia, CA). The mass spectrometry analysis confirmed the desired molecular weight of the reduced form of zampl, i.e., 5158. Purified
5 fractions were frozen and then lyophilized.

The reduced peptide was dissolved in 6 M guanidine HCl (Aldrich Chemical Co.) at an initial concentration of 2 mg/ml. This solution was then added slowly to 2.1 volume equivalents of 1 M guanidine HCl along
10 with 0.52 volume equivalents of DMSO (Aldrich Chemical Co.). The oxidation was monitored with analytical RP-HPLC using the same analytical C18 column; the oxidation was complete at 48 hours. Salts were removed from the reaction mixture using solid phase extraction C18
15 cartridges (Waters, Milford, MA). The eluant containing the oxidized peptide is concentrated and then purified using RP-HPLC semi-prep C18 column (Vydac, Hesperia, CA). Four distinct peaks were determined to correspond to the fully oxidized form of zampl by electrospray LCMS. The
20 peak referred to as peak 2, as it was the second peak to elude by RP-HPLC, was found to contain the conserved defensin disulfide pattern, by a process of elimination using partial digest and peptide mapping of all four peaks. This peak was isolated, frozen and lyophilized.

25 From the foregoing, it will be appreciated that, although specific embodiments of the invention have been described herein for purposes of illustration, various modifications may be made without deviating from the spirit and scope of the invention. Accordingly, the invention is
30 not limited except as by the appended claims.

CLAIMS

WHAT IS CLAIMED IS:

1. An isolated protein comprising a polypeptide that is at least 80% identical to a polypeptide selected from the group consisting of:

a) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 65 of SEQ ID NO:2;

b) a polypeptide having the sequence of amino acid residue 19 to amino acid residue 65 of SEQ ID NO:2;

c) a polypeptide having the sequence of amino acid residue 21 to amino acid residue 65 of SEQ ID NO:2;

d) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 67 of SEQ ID NO:10;

e) a polypeptide having the sequence of amino acid residue 21 to amino acid residue 67 of SEQ ID NO:10; and

f) a polypeptide having the sequence of amino acid residue 23 to amino acid residue 67 of SEQ ID NO:2;

wherein said polypeptide has cysteine residues corresponding to amino acid residues 33, 40, 45, 55, 62 and 63 of SEQ ID NOS:2 or 10.

2. An isolated protein of Claim 1, wherein said protein comprises a polypeptide having the sequence selected from the group consisting of:

a) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 67 of SEQ ID NO:10;

b) a polypeptide having the sequence of amino acid residue 21 to amino acid residue 67 of SEQ ID NO:10; and

c) a polypeptide having the sequence of amino acid residue 23 to amino acid residue 67 of SEQ ID NO:10.

3. An isolated protein having the sequence of SEQ ID NO:10 from amino acid residue 23 to amino acid residue 67.

4. A pharmaceutical composition comprising a protein according to claim 1 in combination with a pharmaceutically acceptable vehicle.

5. An antibody that specifically binds to a protein of Claim 1.

6. An anti-idiotypic antibody of an antibody which specifically binds to a protein of Claim 1.

7. An isolated polynucleotide molecule encoding a protein, said polynucleotide molecule consisting of a coding strand and a complementary non-coding strand, wherein said polynucleotide molecule encodes a polypeptide that is at least 80% identical to the amino acid sequence to a polypeptide selected from the group consisting of:

a) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 65 of SEQ ID NO:2;

b) a polypeptide having the sequence of amino acid residue 19 to amino acid residue 65 of SEQ ID NO:2;

c) a polypeptide having the sequence of amino acid residue 21 to amino acid residue 65 of SEQ ID NO:2;

d) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 67 of SEQ ID NO:10;

e) a polypeptide having the sequence of amino acid residue 21 to amino acid residue 67 of SEQ ID NO:10; and

f) a polypeptide having the sequence of amino acid residue 23 to amino acid residue 67 of SEQ ID NO:2;

wherein said polypeptide has cysteine residues corresponding to amino acid residues 33, 40, 45, 55, 62 and 63 of SEQ ID NOs:2 or 10.

8. An isolated polynucleotide molecule encoding a protein having cysteine residues corresponding to amino acid residues 33, 40, 45, 55, 62 and 63 of SEQ ID NO:10, said polynucleotide molecule consisting of a coding strand and a

complementary non-coding strand, wherein said polynucleotide comprises a nucleotide sequence that is at least 80% identical to the sequence of a polynucleotide selected from the group consisting of:

a) a polynucleotide as shown in SEQ ID NO:9 from nucleotide 220 to nucleotide 420;

b) a polynucleotide as shown in SEQ ID NO:9 from nucleotide 280 to nucleotide 420; and

c) a polynucleotide as shown in SEQ ID NO:9 from nucleotide 286 to nucleotide 420.

9. An isolated polynucleotide molecule encoding a protein having cysteine residues corresponding to amino acid residues 33, 40, 45, 55, 62 and 63 of SEQ ID NO:10, said polynucleotide molecule consisting of a coding strand and a complementary non-coding strand, wherein said polynucleotide comprises a nucleotide sequence as shown in SEQ ID NO:11.

10. An expression vector comprising the following operably linked elements:

a transcription promoter;

a DNA segment encoding a protein of claim 1; and

a transcription terminator.

11. An expression vector according to claim 10 wherein said DNA segment further encodes a secretory signal sequence operably linked to said protein.

12. An expression vector according the claim 11, wherein said secretory signal sequence is selected from the group consisting of:

a) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 18 of SEQ ID NO:2;

b) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 20 of SEQ ID NO:2;

c) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 20 of SEQ ID NO:10; and

d) a polypeptide having the sequence of amino acid residue 1 to amino acid residue 22 of SEQ ID NO:10.

13. A cultured cell into which has been introduced an expression vector comprising the following operably linked elements:

- a transcription promoter;
- a DNA segment encoding a protein according to claim 1; and
- a transcription terminator;

wherein said cell expresses said protein encoded by said DNA segment.

14. A method of producing a protein comprising: culturing a cell into which has been introduced an expression vector comprising the following operably linked elements:

- a transcription promoter;
- a DNA segment encoding a protein according to claim 1; and
- a transcription terminator;

whereby said cell expresses said protein encoded by said DNA segment; and

recovering said expressed protein.

15. An oligonucleotide probe or primer comprising at least 14 contiguous nucleotides of a polynucleotide of SEQ ID NO:11 or a sequence complementary to SEQ ID NO:11.

INTERNATIONAL SEARCH REPORT

National Application No.

PCT/US 98/19222

A. CLASSIFICATION OF SUBJECT MATTER

IPC 6 C12N15/12 C07K14/47 A61K38/17 C07K16/18 C07K16/42
C12Q1/68

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6 C12N C07K A61K C12Q

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	WO 95 32287 A (MAGAININ PHARMACEUTICALS INC. (US); SCHONWETTER B.S.; ZASLOFF M.A.) 30 November 1995	
A	HARDER J. ET AL.: "A peptide antibiotic from human skin" NATURE, vol. 387, 26 June 1997, page 861 XP002072639 cited in the application see the whole document	
A	LEHRER R.I. ET AL.: "DEFENSINS: antimicrobial and cytotoxic peptides of mammalian cells" ANNUAL REVIEW OF IMMUNOLOGY, vol. 11, 1993, pages 105-128, XP000609688	

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

Date of the actual completion of the international search

Box III TEXT OF THE ABSTRACT (Continuation of item 5 of the first sheet)

The present invention relates to polynucleotide and polypeptide molecules for zampl, a member of the beta-defensin family. The polypeptides, and polynucleotides encoding them, exhibit anti-microbial activity and may be used in the study or treatment of microbial infections. The present invention also includes antibodies to the zampl polypeptides.
